The patient states that about two years ago he began to lose weight and energy. He found he was "all in" at the end of the day's work. He consulted his family physician last spring chiefly because of this lack of energy, and after the acute tonsillitis previously mentioned, and following the tonsillectomy, he thought he was worse than before. From June to September 1935 he was at his worst. By September he had determined that he would have to make a change. He decided to take a vacation and drove back to North Dakota to see his family. While he was away he gained weight and felt very much improved. On returning to San Francisco he again took up his work in the mattress and pillow factory. After a short period he began to have his former symptoms; namely, increased fatigue, pain in the long bones, anorexia and loss of weight. Finally he quit work, Jan. 11, 1936. It is striking that at no time has he had any acute chills or other acute symptoms of so-called acute metal fume fever.

**Occupation.**—The patient has been a renovator operator continuously since April 1931. During the first year that he was doing this work, no zinc chloride solution was used in the renovator, steam alone being used for sterilizing the feathers. The process for which the patient is responsible is somewhat as follows: 1. The feathers are washed with tap water and a softener. 2. The feathers are run from the washer into a centrifuge for drying. 3. The feathers are removed from the centrifuge by hand and carried to a table near the renovator. 4. The feathers are then gradually sucked off the table into the renovator, where they are dried further, and then steam, along with zinc chloride solution, is sucked into the renovator. The zinc chloride solution is used as a detergent and sterilizing agent. This solution is made from 3 pounds (1,360 Gm.) of zinc chloride to 1 gallon (4 liters) of water. 5. After the feathers have been processed with the zinc chloride and steam, they are dried and cooled. The renovator is not air tight, and fumes escape from the top of it. This process, however, is carried out in a large room with high ceilings and good ventilation.

**Physical Examination.**—The foregoing history was obtained from the patient on admission and the following observations were made on the same day:

The temperature was 98.4 F., the pulse 76, respiration rate 20, the height 5 feet 10 inches (178 cm.), the weight 182 pounds (82.6 Kg.), and the blood pressure 135 systolic, 90 diastolic.

The patient is well built and well nourished. The head and hair are normal. The skin is of good color and shows no local lesions anywhere. The eyes are normally set and the pupils are equal and regular and react actively to light and in accommodation. The tongue is median and shows no atrophy. The tonsils are out. The nasopharynx is normal. Many of the teeth have been removed. There is considerable metal repair work on the upper left jaw. There is nothing remarkable about the gum margins and no lead line is present. The lymph glands and thyroid are normal. The heart, lungs and pulse show no abnormalities. The abdomen presents no localized tenderness. The liver and spleen are not palpable. The joints and spine are normal. The deep reflexes are equal and active throughout.

Routine urine examination showed an acid reaction, a specific gravity of 1.010, no albumin or sugar, and a negative microscopic test. The blood Wassermann reaction was negative.

Examination of the blood showed: hemoglobin 85 per cent, red blood cells 4,590,000, color index 0.94, white blood cells 11,550, slight achromia; slight polychromatophilia, and no nucleated red cells. The differential count revealed polymorphonuclears 51 per cent, of which 47 per cent were mature; lymphocytes 45 per cent, monocytes 1 per cent and eosinophils 2 per cent. There was slight stippling of the red cells. Apparently this was not as marked as it was in the previous blood examination of January 10.

Dental roentgenograms showed no evidence of periapical abscesses but some absorption of the alveolar processes.

Previous to my examination, certain laboratory determinations had been made on this patient, Jan. 10, 1936. At that time a blood examination gave the following results: hemoglobin 69 per cent (Sahl), red blood cells 3,650,000, color index 0.9, white blood cells 8,100, differential count: polymorphonuclears 57 per cent, small lymphocytes 21 per cent, large lymphocytes

18 per cent and monocytes 4 per cent. Study of the blood smear showed the following: the red blood cells were mostly microcytes; there was slight achromia, with one stippled cell to each 10,000 red blood cells, and moderate poikilocytosis. No erythroblasts were seen; platelets were reduced in size and number; no malarial parasites were seen; the white blood cells showed the distribution of the polymorphonuclears as follows: 50 per cent adult cells; 60 per cent immature and 10 per cent stab cells; three myelocytes were seen; polymorphonuclears showed toxic granules; no myeloblasts were seen; lymphocytes and monocytes were normal. February 3, examination of the urine was negative for lead and arsenic. Zinc was present, but in too small amounts to be estimated quantitatively.

#### INSPECTION OF THE PILLOW DEPARTMENT OF THE MATTRESS FACTORY

April 10, 1936, I visited the factory where the patient was employed to inspect the process of sterilizing the feathers in the renovator.

I was particularly inquisitive about the making up of the zinc chloride solution used in the renovator. It was a part of the patient's duties to make up this solution by hand. The zinc chloride is obtained in 100 pound drums, and fresh solutions of this material are made about three times a week. This is done by dipping the crystalline zinc chloride powder out of the stock drum by hand, without gloves. After the zinc chloride powder has been removed from the drum, water is added to it and the finished solution is then stored in a small barrel with an outlet spigot. From this barrel the solution is drawn off into a mason jar as needed. This mason jar containing the zinc chloride solution is placed near the renovator, and the solution is drawn in along with the steam in the process described.

The zinc chloride in the solid form as it comes from the drum is obviously a very hygroscopic salt of zinc. When a small amount of this powder is placed on the finger, the finger becomes moist and takes on a greasy feel within a minute or two. When a small amount of this material has been exposed to the atmosphere on the hand, ordinary washing with soap and water will not remove it, whereas washing with a 5 per cent solution of hydrochloric acid is effective in its removal. The precaution of immediately washing the hands with the weak acid solution has not been followed, since it has never been recognized that there was a metal hazard involved in this work. Besides the likelihood of exposing the hands to the zinc chloride solution when it is being made up, it is obvious that in filling and carrying the solution in the mason jar from the stock barrel to the renovator the fingers would be exposed to the splashing of the fluid. As already noted, the patient has had complete charge of making this solution and using it since 1932.

#### CONCLUSIONS

From the examination it appeared probable that I was dealing with a toxic condition which had been brought about by the exposure of the hands in the making of the solution of zinc chloride used in the renovator. From the nature of the zinc chloride and the carelessness that had been exhibited in the exposure of the hands and forearms to this chemical, it was obvious that the patient had ample opportunity, over a period of four years, to absorb toxic amounts of zinc. Clinically, the picture presented was not unlike some of the instances recorded by McCord in his study of chronic zinc intoxication. At the time when my examination was made it appeared that the patient was improving. The blood changes were not so striking as they were January 10. In the meantime he had had treatment for his anemia, and he had not been further exposed to zinc. In association

excellent results of Elliott.<sup>1</sup> On the other hand, the results with local destruction here compare very favorably with the results with radium alone or surgery alone at this clinic, and much better than with roentgen therapy alone.

The methods employed in actual destruction of the local lesion at this clinic are, briefly, curet and wide cauterization with the actual cautery, curet and chemical cautery with a strong acid such as trichloro-acetic or acid nitrate of mercury; electrodesiccation of the local lesion including from one-fourth to one-half inch of normal lip, and, lastly, adequate removal with the electric cutting current followed by cauterization of the bleeding exposed surface.

Local destruction requires no loss of time from work, and no hospitalization or expensive equipment. Local anesthesia was adequate in almost every case. The traumatic ulcers that result from the treatment healed with boric compresses in almost every case in from two to four weeks, with a surprisingly excellent cosmetic and a perfect functional result. These reasons add further to the advantage of local destruction over other methods.

#### ROENTGEN AND RADIUM THERAPY

Of forty-six previously untreated cases treated by this method, thirty-five cases have been followed, five by radium and thirty by roentgen therapy. Approximately 25 per cent of these were proved by biopsy.

#### RADIUM THERAPY

Five early cancers of the lip were treated here by radium therapy in one of which roentgen therapy was given to the regional lymph nodes. Three were cured for five years or more. The immediate recurrence that appeared in the fourth case was destroyed by local cautery to result in an eight year cure. The palpable lymph nodes that appeared in the fifth case were removed surgically to show microscopic evidence of metastasis. This case was still recurrent with metastases after four years. The cosmetic results in the three cases with five year cures were excellent.

Radium therapy for early epithelioma of the lip has been advocated by many.

This excellent method of treating cancer of the lip has many things in its favor. The method requires no hospitalization. It is free from pain, hemorrhage and shock. In competent hands the method is almost free from danger. The cosmetic results are certainly as good as if not better than with any other form of therapy. One limitation of its use is that in untrained hands recurrences of a particularly intractable type are common. Attention should be drawn to the poor results obtained here and elsewhere in recurrent cancers of the lip following both radium and roentgen therapy. The expense of radium and radon seeds when indicated, moreover, will limit, at least for the time being, its use to large clinics and the occasional prosperous patient.

#### ROENTGEN THERAPY

The thirty previously untreated cancers of the lip treated by local roentgen therapy with or without roentgen therapy to the regional lymph nodes consisted of fourteen early, eleven moderately advanced, and five far advanced cases.

Of the fourteen early cases death had occurred in three, or 21.4 per cent, of which two were due to cancer of the lip. The enlarged lymph nodes that occurred shortly after the roentgen therapy in one case were removed by surgical dissection and proved to be metas-

tases by pathologic examination. This case was still progressively metastatic after three years. An apparent cure in eleven, or 78.5 per cent, for from one to eight years, of which two were five year cures, was obtained in these fourteen cases.

Four of the eleven moderately advanced cases ended fatally, two of which had recurred immediately and death was due to carcinoma of the lip. One case was still active despite subsequent roentgen therapy. An apparent cure of eight, or 72.7 per cent, for from one to three years was obtained in this group.

In two of five far advanced cases, cancer of the lip proved fatal; the immediate recurrence with metastases which appeared in one case was still active when last seen. Two patients were cured, of whom one died of intercurrent disease after eight years.

The results with surgery plus dissection of the regional lymph nodes and local destruction as carried out here were better than the results reported by Schreiner and Mattick<sup>16</sup> with radiation therapy and certainly were much better than those with irradiation only in our series.

For economic reasons, adequate roentgen therapy in cancer of the lip is limited to large clinics, the same as radium, and is therefore not so available as locally destructive methods. Under all but the best trained workers, recurrence of a particularly dangerous type is a not infrequent occurrence. The severe reactions from toxic absorption from the destroyed cancer cells, the almost unbearable dry mouth in most cases from inhibition of the salivary glands, and the possibility of roentgen dermatitis with possible malignant changes are certainly not in its favor. Roentgen dermatitis in cases treated by heavy dosage has been noted in our group in at least a few cases.

From table 3, a comparison of those cases treated by surgical excision, surgical excision plus regional lymph nodes and local destruction, and like groups in which these forms of treatment were combined with roentgen therapy to the regional lymph glands, it is our opinion that roentgen therapy is of little if any use as a prophylaxis against metastasis.

In those cases in which there are definite palpable nodes, we advocate surgical dissection of the regional nodes. We do not advocate roentgen therapy to these nodes.

In those cases in which large fixed metastatic nodes are present there is no choice. These cases are almost invariably hopeless. High voltage roentgen therapy or radium or radon implants may in the occasional case retard growth of the metastasis.

#### RECURRENT CASES

One hundred and sixteen recurrent cases were seen in this series. Of these, sixteen cases were not treated at this hospital. Most of the latter were moderately or far advanced cases with probable metastases in which treatment was considered futile.

Of the 100 recurrent cases in which treatment of one kind or another was given here, local therapy either surgical or chemical or actual cautery was given in sixty-five, and radiation therapy either roentgen-ray or radium was given in thirty-five prior to coming to this clinic.

Of the sixty-five that had received local therapy prior to therapy here, twenty-two were treated further with local destruction, nineteen by radiation therapy, nine by surgical excision, and fifteen by surgical excision plus the removal of regional nodes at this clinic. In a

per cent of the drug is excreted in the urine; 67 per cent is evacuated in the feces. According to Lamson and Ward<sup>4</sup> a therapeutic dose (1 Gm. of the crystoid for adults and children over 10 years of age in hard gelatin capsules of 0.2 Gm. capacity each) is from 90 to 100 per cent efficient in removing *Ascaris*, from 80 to 85 per cent for hookworms and from 40 to 45 per cent for *Trichocephalus*. No pretreatment preparation of the patient is necessary. The drug is taken on an empty stomach in the morning and food is proscribed for five hours. For ascariasis and heavy hookworm infection a post-treatment saline purge is recommended. If instructions are heeded not to chew the capsule before swallowing and to fast for five hours after taking the drug, no toxic symptoms will be experienced.

**Ficin** (the active principle of *leche de higueron*).—*Leche de higueron* is the crude sap obtained from *Ficus laurifolia* and related species of this genus in Central America and South America. For centuries it has been an Amerind household remedy for intestinal worms. Ficin, the active principle,<sup>5</sup> is a proteolytic enzyme which is particularly effective in removing *Trichocephalus* from the intestine. On account of its rapidly fermenting properties, the crude sap is not available for anthelmintic use in the United States. Ficin is an acetone-extracted yellowish white powder, which is temporarily irritating to the intestinal mucosa but on intimate contact with the intestinal epithelium for fifteen minutes fails to produce erosion. If this product is made available for the medical profession it may provide a relatively nontoxic specific anthelmintic for *Trichocephalus* and *Enterobius*, for which no satisfactory drug is now provided.

**Gentian Violet, Medicinal**, N. N. R.—Gentian violet is either pentamethyl or hexamethyl rosanilin or a mixture of the two in at least three parts of the dye to one part of dextrin. For biologic certification it must have sufficient bacteriostatic power to prevent growth of *B. subtilis* on nutrient agar when added to the agar one part in a million. Although the dye was originally used as a systemic and urinary antiseptic, it was found by Faust and Yao (1926) to be specific for the Chinese biliary fluke *Clonorchis sinensis* and by DeLangen (1928) and Faust (1930) for *Strongyloides stercoralis*. In strongyloidiasis the orally administered dye penetrates and stains the mucosa of the intestinal wall, where the female worms are lodged, in proportion to the amount of free dye available at the particular level of the bowel. If the dye reaches the worms in sufficient concentration, they are stained and soon die. Excessive amounts of gentian violet irritate the gastric and duodenal mucosa and produce nausea. The therapeutic dose (0.06 Gm. enteric-coated tablets three times a day for sixteen and two-third days) is usually well tolerated; only a small percentage of patients experienced temporary intestinal discomfort and nausea. The dye may also be intubated as a 1 per cent solution in 25 cc. amounts into the duodenum, with curative results following one to three intubations.<sup>6</sup>

**Oleoresin of *Aspidium*** (oleoresin of male fern), U. S. P.—Decoctions and extracts of *Aspidium* were used as anthelmintics by Greek and Roman physicians.

U. S. P. oleoresin is obtained as an ether extract from the rhizomes and stipes of *Dryopteris filix-mas* (syn. *Aspidium filix-mas*) and to a lesser extent from other species of this genus of fern. The oleoresin should be fresh in order to contain a standard 24 per cent of filicin in amorphous form, the active anthelmintic principle. This drug is very irritating to the gastro-intestinal mucosa, frequently producing vomiting and at times dysentery; it may cause jaundice and at times necrosis of the liver; it rapidly paralyzes nonstriated muscle; it slows and weakens heart action; it stimulates the spinal cord with resultant twitching, possible convulsions and respiratory paralysis. In therapeutic doses (from 1.8 to 3.6 cc. in doses of from 0.6 to 1.2 cc. given at half-hour intervals on an empty stomach) oleosin of *aspidium* is an efficient drug for removing tapeworms from the intestine. The diet for two days previous to treatment should exclude absorbable fats. Post-treatment saline purgation should be ordered. Toxic symptoms from a therapeutic dose may include headache, vertigo, bilirubinemia and jaundice, vomiting or dysentery, dyspnea and albuminuria. Occasionally severe abdominal cramps; convulsions, loss of reflexes, optic neuritis or blindness may be experienced and death may result from respiratory or cardiac paralysis. The drug is contraindicated in anemia, debility, old age, infancy and pregnancy.

**Pelletierine Tannate**, U. S. P.—This drug is a yellow amorphous odorless powder, consisting of "a mixture of the tannate of the several alkaloids obtained from pomegranate, *Punica granatum*" (U. S. P. XI, p. 278)<sup>1</sup> derived from the bark or stem. In small doses it produces vomiting and colicky diarrhea, headache, vertigo, drowsiness and diplopia. In addition, toxic doses cause weakness of the limbs and ascending paralysis. It is administered as a decoction containing 0.25 Gm. on an empty stomach. It is believed to be especially good for removal of the pork tapeworm, *Taenia solium*, but is ineffective for *Hymenolepis nana*. Before and during treatment, alcohol is proscribed. It is contraindicated in pregnancy.

**Antimony and Potassium Tartrate**, U. S. P.—Antimony and potassium tartrate (tartar emetic) "contains not less than 99 per cent  $\text{KOOC} \cdot \text{CHOH} \cdot \text{CHOH} \cdot \text{COO}$  (SbO).  $\frac{1}{2}\text{H}_2\text{O}$ " (U. S. P. XI, p. 57).<sup>2</sup> The common toxic symptoms produced by it include severe cough, a metallic taste, nausea, vomiting, diarrhea and muscular and arthritic pains. Less commonly the patient has manifestations of jaundice, cyanosis, rapid pulse, a choking feeling in the chest, tachycardia and severe headache. The sodium salt is slightly less toxic but is less stable; the pentavalent aromatic compounds of antimony are much better tolerated. Antimony and potassium tartrate and sodium antimony tartrate must be made up fresh before each administration and must be introduced very slowly by the intravenous route. Neo-antimosan (pyrocatechin sodium disulfonate of antimony), distributed under the trade name "fuadin," can be administered intramuscularly without local necrosis. Antimony and potassium tartrate and the related salts of antimony are specific anthelmintics in the treatment of schistosomiasis; they are also stated to relieve fever and myositis in trichinosis (Grove, 1925), and patients suffering from dracunculosis are believed to be benefited by four or five intravenous injections on alternate days of 0.06 Gm. of antimony and potassium tartrate (Macfie, 1922).

6. Faust, E. C.: *Strongyloides* and *Strongyloidiasis*, *Rev. de parasitol. clin. y lab.* 2: 315 (May-June) 1936.

tures should be considered as potentially malignant and should be treated early by local destruction in all cases.

3. Treatment in early cancer of the lip assures a high per centage of cures if the lesion is completely destroyed.

4. The results of treatment of early cancer of the lip in this series were excellent with local destruction or with surgical removal plus dissection of the regional lymph nodes, were good with surgical excision alone or with radium therapy, but were only fair with roentgen therapy.

5. For economic reasons we feel that the treatment of choice in early cancer of the lip without enlarged lymph nodes is local destruction.

6. The results in the moderately advanced lesions, though fair, were not as good as in the early lesions, and the best results were achieved by surgical excision plus removal of the suprahyoid nodes.

7. The results in the far advanced cases except for the rare case were extremely poor. No case presenting invasion of the mandible has been cured.

8. The previously untreated cases did better than cases in which local therapy was administered prior to treatment here and much better than those in which inadequate radiation therapy had been given before their treatment here.

9. Metastases were almost never found in early cases without palpable nodes and rarely in the moderately advanced cases without palpable nodes.

10. Surgical dissection of the regional lymph nodes is indicated only in those operable cases presenting palpable nodes in which the latter are not fixed.

11. Surgical dissection of the suprahyoid nodes in this series gave close to 40 per cent five year cures in cases presenting positive nodes.

12. High voltage roentgen therapy to the regional lymph nodes was by this study found to be unnecessary in cases without palpable nodes and useless when metastasis had occurred.

13. The study of the cell type in cancer of the lip was found to be useful as an aid in determining prognosis and the form of treatment.

#### ABSTRACT OF DISCUSSION

DR. EVERETT S. LAIN, Oklahoma City: Those who attended the meetings of this section at St. Louis in 1922 will recall Dr. Bloodgood's discussion when I presented the same subject with a report of 248 cases. It resulted in the usual bitter attack on the radiologist's method of treating lip cancer as contrasted with the surgical method. Today's presentation is an excellent commendation of the surgical technic. On the other hand, it is not so complimentary to their radiation technic, nor do they report a sufficient number of cases (thirty-five) to base a fair opinion as to the radiologic treatment. They do not tell us the technic of their radiation treatment. Whereas surgical technic is fairly well standardized, radiation methods have been constantly improving, and only within the past five or seven years have they become even comparatively standardized. Cures have been increasing since the introduction by Coutard of methods of radiation, further advocated by Clark, Pfahler and others. I cannot fully agree with the conclusion that the prognosis in lip cancer in the young is better than in the aged. This is contrary to the behavior of cancer in other parts of the body. I am more inclined to attribute their favorable results in the young to the early seeking of treatment. The young person has more pride in his appearance and will naturally call on a doctor when he has a lesion on his lip, especially in view of the possibility of an extragenital chancre. The reports

of other clinics which the authors have quoted, and which I have recently reviewed, are a commendation on preoperative and postoperative irradiation in association with the surgical removal of the primary lesion and the lymph nodes. I want to endorse fully all that was said about surgical diathermy and diathermic coagulation methods which they use in the destruction of the lip cancer. It is a short method and just as effective as irradiation in the group of early cases, though I cannot agree that the cosmetic results are equally good. I cannot help but believe that, in their second group of cases, the infiltrating type, in the private practice of Drs. Wile and Hand, where they have personal supervision over the daily applications of interstitial radium needles or radium packs, they obtain better results than those reported from their university hospital. I believe that both dermatologists and surgeons would obtain better results if they cooperated and more frequently held counsel over all the questionable cases. The treatment should be individualized for each case in which there is a possibility of metastases.

DR. RICHARD L. SUTTON SR., Kansas City, Mo.: I agree with Dr. Lain that the statistics in my office would indicate that the lesions are much worse if untreated and that the outlook is much worse in the young than in the old. Otherwise I cannot agree with Dr. Lain. My experience with regard to the classification types 1 to 4 of Broders parallels that of Dr. Hand and Dr. Wile. My assistants and I have a good deal of trouble now (we used to have a great deal more), on account of marked lymph node involvement, with the old fashioned doctor: not necessarily the country doctor—the city doctor as well was to blame. The doctor would say to a patient with a cancer of the lip "Don't bother that until it bothers you." When the patient gets to somebody who recognizes what the condition is, he has enlarged lymph nodes under his chin and not much can be done for him. We have learned more about the successful treatment of cancer from one of the pioneers in this country than from anybody else, and I am glad that he is here this morning—Dr. James F. Percy of the Pacific Coast. With regard to the use of radium and x-rays we often have recourse to these agents, before and after, but as I tell my students at school I really believe that if a man would start out with a small Percy cautery or, as he graduated in wisdom, go up to a stronger one, he would cure more cancers than with any other one agent in the whole world.

DR. JAMES F. PERCY, Los Angeles: My dermatologic colleagues on the coast make mistakes. Some of them are kind enough, when they get too far along, to send some of these patients to me, and by the use of the cautery method I have been able to salvage a rather large proportion of them. I look on lip cancer as a disease that ought to be cured in a large percentage of cases. The thing that must be done in all cancer is to do the big thing first. There exists only one good chance at cancer and that is the big operation early. I am devoted to the cautery. It was proved long ago that the cancer cell cannot be transplanted after it has been heated to 113 F. (45 C.) for ten minutes, and that is what isn't done; the heat isn't infiltrated; none of these operations are done big enough. I have treated about 900 cancers of the lip with the cautery. I do most of them without an anesthetic. I heat the cautery knife to from 1,200 to 1,500 F., which is determined by sticking the knife into tincture of green soap for a distance of a quarter of an inch. At that temperature it will not hiss when it enters the soap and nothing will stick to it when it is removed. One can put that on the lip, first covering the eyes of the patient, and the patient won't have any pain. The important point, after the diseased area has been removed, is the infiltration of the heat at a lower temperature, about 700 or 800 F., into the bed of the remaining tissue with my ball-tipped cautery, until there is a horn or leather-like surface. This leather-like surface should be kept free from saliva as far as possible for two weeks; otherwise it will be digested. Two weeks is required for the normal repair cells to be deposited under this horny layer, after which the extremities of the wound in the lip should be pressed intermittently with the fingers toward the center for three or four minutes morning and evening. For the first few days this should be done gently,

common lead pencil. The infection has a cosmopolitan distribution but is most common in warm countries and is particularly prevalent in children under 10 years of age. Both sexes have three conspicuous triangular lips at the anterior end of the body. The female is appreciably larger than the male, which has a posterior ventral curvature. *Ascaris* is a lumen parasite of the small intestine. The female lays about 100,000 eggs daily. The fertilized but unembryonated eggs, when deposited on moist soil, embryonate slowly for several weeks, following which they are found to contain motile infective stage larvae, which, however, hatch normally only after ingestion and arrival in the small intestine. The escaping larvae migrate through the intestinal wall and are carried through the lymphatics or blood stream to the lungs. Escaping from the pulmonary capillaries into the bronchioles, they are carried up to the epiglottis and down through the esophagus and stomach to the small intestine, where they develop into adult worms. Mature ascarids, single or in multiples, may or may not produce symptoms. Acute symptoms are usually due to the worms becoming irritated and entangled into a mass, or migrating into unusual foci, as the common duct or the appendiceal lumen, or perforating the intestinal wall. Toxic manifestations or pronounced allergy may result from *Ascaris* infection. Specific diagnosis consists in identification of the eggs by microscopic examination of the feces. The drug of choice in ascariasis is hexylresorcinol (1 Gm. for an adult, from 0.2 to 0.8 Gm. for children under 10 years of age, in hard gelatin capsules), administered on an empty stomach with a post-treatment saline purgation and no food for five hours. This drug is much less toxic than either santonin or oil of chenopodium, is much more efficient than santonin and is as efficient as oil of chenopodium. Since infection usually results from oral contamination with soil "seeded" with infective-stage *Ascaris* eggs as a result of previous promiscuous defecation, ascariasis usually produces a vicious cycle, particularly in small children. Prevention therefore consists in educating small children to use sanitary toilets, privies or latrines.

#### WHIPWORM INFECTION (TRICHOCEPHALIASIS)

Trichocephaliasis in man is produced by the nematode *Trichocephalus trichiurus* (syn. *Trichuris trichiura*), which occurs typically with its head embedded in the wall of the cecum and appendix, less frequently the posteriormost levels of the ileum, or the colon. The worms have a length of from 35 to 50 mm. and are threadlike in their anterior half and fleshy in their posterior half. The females have a club-shaped posterior extremity; the males have a posterior watch-spring coil. Each day the female lays a few thousand barrel-shaped eggs with bipolar mucoid plugs. When evacuated in the feces these eggs are unembryonated, but on favorable moist ground they embryonate slowly and in a few weeks or months become infective. When these infective-stage eggs are accidentally swallowed by human beings they hatch in the small intestine, and the emerging larvae gradually pass down in the intestine and without need for migration soon reach the cecum or nearby level of the intestine, where they become attached and grow into adults. Light infections usually produce no significant symptoms, although individual cases occasionally show signs of systemic toxemia. Very heavy infections, which are rarely seen in the United States, may produce a syndrome

simulating hookworm disease. There is no satisfactory chemotherapeutic available for use by physicians in treating this infection, although *leche de higuera* (2 fluidounces, or 60 cc., taken on an empty stomach), or the equivalent amount of ficin, has been demonstrated to be extremely satisfactory. In the United States trichocephaliasis is not a public health problem.

#### SEATWORM INFECTION (PINWORM INFECTION, OXYURIASIS)

Seatworm infection is cosmopolitan in distribution. It is produced by *Enterobius vermicularis* (syn. *Oxyuris vermicularis*). The young adult worms live attached to the wall of the distal portion of the ileum, less commonly of the cecum and appendix. These worms are considerably smaller than hookworms. The females have an acuminate posterior end; the smaller males have the posterior extremity curved ventrally. Gravid females lose their attachment to the intestinal wall and become migratory forms. They seldom lay their eggs within the bowel, but in migrating out of the anus at night they crawl in the perianal and perineal folds, setting up an intolerable pruritus which invariably provokes scratching. The integument of these worms is then usually ruptured and the eggs are dispersed, soiling the skin of the area, the fingers, the clothing and the bed linen. When discharged, the eggs are usually fully embryonated and infective. Soiled fingers contaminate the mouth and cause reinfection of patients; soiled clothing and bed linen, as well as toilet seats, serve to cause infection of other persons in the same family or institution. Symptoms due to the infection within the intestine are usually infrequent and relatively mild; nervousness, insomnia, loss of appetite and more serious constitutional manifestations frequently result from the excursions of the gravid female worms. Diagnosis may be made from microscopic identification of the characteristic eggs in the feces (considerably less than 5 per cent of the cases) but usually depends on recovery of the female worm migrating out of the anus. The treatment of choice consists in (1) oral administration of hexylresorcinol crystalloids (as recommended for ascariasis), followed the same night by a high retention enema of an alkaline solution (1:1,000) of the crystals which has been preceded by an ordinary water enema to evacuate feces from the large bowel. Several such courses of treatment are frequently needed to eliminate the infection. Children are most commonly infected. They should use closed sleeping garments, which should be frequently sterilized by boiling, their finger nails should be clipped close and kept clean, and they should be taught to wash their hands thoroughly each time after visiting the toilet and before meals. Only by enforcing such rules of personal hygiene can seatworm infection be eradicated.

#### STRONGYLOIDIASIS (STRONGYLOIDOSIS)

Strongyloidiasis is caused by *Strongyloides stercoralis*. It is usually prevalent in warm moist communities of the world and is not uncommon in the southern part of the United States and in the American tropics. The parasitic female worms typically inhabit the mucosa of the intestine, most frequently at the levels of the duodenum and jejunum. There they lay partially embryonated eggs, which usually hatch in the bowel wall and liberate motile larvae, which are discharged in the feces. In favorable soil these larvae either metamorphose directly into infective-stage larvae or develop into free-living adults, which in turn produce

## CHRONIC ZINC INTOXICATION

AN INSTANCE OF CHRONIC ZINC POISONING  
FROM ZINC CHLORIDE USED IN THE  
PILLOW MANUFACTURING  
INDUSTRYERNEST S. DU BRAY, M.D.  
SAN FRANCISCO

Brass founders' ague, spelter shakes and brass chills have long been known to be caused by the fumes in the founding of brass and the smelting of zinc. The condition is now called metal fume fever and is caused by the inhalation of zinc oxide fumes. The symptoms of metal fume fever come on a few hours after exposure, usually after the workman has reached home. Alice Hamilton's<sup>1</sup> description of the clinical picture of the attack is illuminating. "Chilling of the body is often the exciting cause, and the cases are always more numerous in winter, although this is partly due to the better ventilation of the foundry in summer. The actual chill is preceded by a sense of dryness in the throat, with cough, and a sense of lassitude and oppression in the chest, sometimes nausea, rarely vomiting. The Russians have found that a warm bath taken at this stage may avert a chill. The chill is followed by sweating and more or less prostration, but the man usually goes back to work. The temperature, according to Drinker's observations, is hardly ever over 101 F., reaching its maximum in ten or twelve hours after the inhalation of the fumes. The leukocytosis persists longer." Drinker and Fairhall<sup>2</sup> state that "a single industrial condition arises from zinc and this condition is not produced by zinc alone. This is the 'zinc chill,' better known as 'metal fume fever.' The different groups of symptoms described as chronic industrial zinc poisoning, together with other complexities which have been ascribed to zinc, may be disregarded, as they are due to a contamination by other substances." Nevertheless, studies of groups of brass workers show that their health is below the average for their class.

Zinc has the lowest boiling point of all the industrial metals, giving off fumes at about 500 C. It is volatilized zinc that causes industrial poisoning in zinc smelting, in brass founding, in brazing, in galvanizing and in oxyacetylene autogenous molding. The poisonous agent is the flaky oxide of zinc that forms as the fumes cool. The mechanism by which the acute symptoms of metal fume fever are produced has been disputed. According to Lehmann,<sup>3</sup> since zinc oxide is itself harmless and brass chills are followed by a rise of temperature which does not follow exposure to other metallic poisons, and since the result is immunity, not accumulative poison, the theory is propounded that this is not, strictly speaking, a zinc poisoning but occurs as follows: As the fumes cool, zinc carbonyl is formed, which is hygroscopic, and as it spreads over the lungs it sears the surface cells, and it is the resorption of the toxalbumins from these destroyed cells that accounts for the symptoms of so-called brass poisoning.

Besides the aforementioned acute metal fume fever (brass founders' ague) the subject of chronic intoxication with zinc has been seriously considered. One of the most convincing reports that such a chronic intoxica-

tion can be brought about in those exposed to zinc compounds over a long period is that of McCord,<sup>4</sup> whose work was based on a study of the crews of two galvanizing plants in which sheet metal was coated with molten zinc. Strange to say, in galvanizing, acute zinc poisoning is rare under normal operating conditions, although zinc fumes arise in abundance because of the low temperature required to generate these fumes at 468 C.

In the chronic cases of zinc intoxication studied by McCord, the gastro-intestinal symptoms predominated in the clinical picture. Such complaints as nausea, vomiting, pain in the epigastrium, anorexia and loss of weight were the most common. Of these nausea and vomiting were particularly constant complaints in the twelve case histories presented in this report. Hypochromic anemia was also present in several cases, whereas basophilic degeneration in the red cells was much less commonly encountered than in his series of cases of lead poisoning. Zinc was found in pathologic amounts in several cases in which it was determined in the urine.

The following case is presented for its interest as an unusual source of probable chronic zinc intoxication in the pillow manufacturing industry. As will be noted, the portal of entry of zinc in this case was believed to be absorption through the skin of the hands and forearms after occupational exposure of these parts to zinc chloride over a period of several years. The inhalation source of intoxication was unlikely, because the temperature produced in the renovator was not sufficient to volatilize zinc in appreciable quantities.

## REPORT OF CASE

*History.*—A married man, aged 34, engaged as a renovator operator in a mattress and pillow factory, complained April 3, 1936, of a general "run-down condition" and fatigability. He stated that during the past two months, since he had stopped work, these complaints were very much less marked. His appetite had also improved and he was not having the pains in the long bones of the lower extremities that were so troublesome the summer and fall before.

The patient's father was living and well in North Dakota. His mother had died of pneumonia at the age of 51. He had three brothers and four sisters living and well. The patient's wife and two children also were well. He came to California in 1929 from North Dakota. During all of his California residence he had worked in the aforementioned mattress and pillow factory.

His past health had been good. He had had the usual diseases of childhood but none of the more serious infectious diseases. In the spring of 1935 he had a rather severe attack of acute tonsillitis. May 30, 1935, the tonsils were removed. He was not subject to headache. The eyes and ears were good; he did not wear glasses. Many of the teeth were out; three had recently been removed; that is, in December 1935. The patient stated that these teeth were removed because the fillings had dropped out and he could not afford to have them crowned.

The appetite is now good; it has improved since he stopped work on Jan. 11, 1936. The bowels are also fairly regular; previously they were constipated. He has no cardiorespiratory symptoms, such as cough, sweating or palpitation. There is no nocturia. There was no history of venereal diseases.

At present he has no joint symptoms. Last summer one of his prominent symptoms was aching in the bones of the lower extremities. When he took a vacation from his work in September and October 1935 this pain disappeared, only to return again when he resumed work in November.

The patient sleeps well. His average weight was 190 pounds (86 Kg.) until two years ago. His present weight is 182 pounds

inflammatory reactions, abscesses and pseudotubercle formation. *S. haematobium* infection results in serious functional impairment of the urinary bladder and adjacent tissues. In *S. mansoni* and *S. japonicum* infections the intestinal wall and liver are most seriously involved. Hepatic cirrhosis, ascites and splenomegaly are usually found in the later stages of the intestinal schistosomiasis. Diagnosis is based on microscopic identification of the typical eggs in the urine or feces.

The drug of choice in all three of these diseases is antimony and potassium tartrate or sodium antimony tartrate by vein or neoantimonan intramuscularly. A complete course of treatment usually kills the worms and allows them to be absorbed, but specific therapeutics is of little avail in old chronic cases in which advanced intestinal and hepatic involvement has occurred.

#### FASCIOLIASIS (SHEEP LIVER-ROT) AND FASCIOLOPSIASIS

Fascioliasis is produced by a large biliary fluke, *Fasciola hepatica*, which has a cosmopolitan distribution wherever sheep are raised but only incidentally infects man. The mammalian host acquires the infection from ingesting raw vegetable matter to which the post-cercarial cysts have become attached. Infection produces a necrosis of the liver parenchyma, hypertrophy of the biliary ducts with the development of fibrous adventitia around them, and eventual portal cirrhosis. There is no eminently satisfactory chemotherapeutic agent for this infection in man, although Khouri and Basnuevo (1935) claim satisfactory results after administration of emetine hydrochloride.

Fasciolopsiasis, caused by *Fasciolopsis buski*, is a fluke infection common in certain areas of China and other parts of the Far East. It is acquired from raw consumption of certain aquatic plants. The large fleshy flukes live attached to the wall of the duodenum and jejunum, where they frequently produce a profound systemic toxemia. Carbon tetrachloride is the drug of choice. When administered as in hookworm infection it produces a high percentage of cures.

#### CLONORCHIASIS AND OPISTHORCHIASIS

Clonorchiasis is produced by *Clonorchis sinensis*, a small bile duct fluke prevalent in man, dogs and cats in the Far East. Opisthorchiasis is caused by *Opisthorchis felinus* in East Prussia, Siberia, the Balkan states and probably other areas, and by *O. viverrini* in northern Siam. All these worms are acquired from eating raw infected fresh water fishes. The presence of the worms in small numbers in the bile passages provokes slight hypertrophy and fibrosis of the walls of the distal bile ducts; only in heavy infections are there symptoms indicative of extreme involvement of the liver.

Gentian violet medicinal and antimony salts are lethal for these worms, provided these therapeutic agents reach the worms in lethal amounts within the tolerance of the patient. In recently acquired infections treated with these chemotherapeutic drugs the prognosis is good. In chronic infections in which the worms have become walled off in the bile ducts by fibrous tissue deposits about the duct walls, reduction in the number of worms may be effected but cure is doubtful.

#### HETEROPHYDIASIS AND METAGONIMIASIS

Heterophydiasis and metagonimiasis are caused by species of the superfamily Heterophyoidea. One or more species of these small flukes occur as an infec-

tion of man, dogs, cats and other animals in the Far East, Siberia, Egypt, the Balkan states and other regions of the Eastern Hemisphere. Infection is acquired from eating infected raw fish (usually fresh-water species). The worms are relatively transitory parasites of the mucosa of the small intestine and can be readily removed by carbon tetrachloride or tetrachlorethylene as administered in hookworm infection. The danger of the minute eggs of these species getting into the circulation and filtering out in the myocardium, with the production of a pseudoberiberi syndrome, has been recently demonstrated by Africa, Garcia and de Leon.<sup>8</sup>

#### PARAGONIMIASIS (PULMONARY DISTOMIASIS)

Paragonimiasis is produced by *Paragonimus westermani*, a fluke that parasitizes human, canine and feline hosts in the Far East and has been introduced into Venezuela in recent times. It results from eating the tissues of infected crabs or crayfishes which harbor the encysted stage of the parasite. The organism is somatic in its habitat, typically residing in the lungs, although it may develop in the abdominal viscera or even in the brain. It produces abscesses and fibrous tissue formation. Eggs are usually discharged in sputum together with blood and mucus. Although emetine hydrochloride has been claimed to be remedial in cases of paragonimiasis, there is no proof that this drug is curative for this infection.

#### SUMMARY

1. Beta-naphthol, thymol, oil of chenopodium, carbon tetrachloride, tetrachlorethylene, santonin, hexylresorcinol, ficin and gentian violet are the most important chemotherapeutics useful in removing intestinal nematodes. Of these, tetrachlorethylene is probably the safest efficient drug for hookworm infection, and hexylresorcinol for ascariasis and seatworm infection. Gentian violet is the only known specific for strongyloidiasis. Ficin would probably be the drug of choice in trichocephaliasis but it is not as yet available for use by the medical profession. Oil of chenopodium is very potent for both hookworm infection and ascariasis, and carbon tetrachloride for hookworm and tapeworm infections, but both drugs are highly toxic and are frequently contraindicated.

2. Oleoresin of aspidium and pelletierine tannate are commonly employed in removing tapeworms. Both are highly toxic and are at times contraindicated. Probably oleoresin of aspidium is the drug of choice in these infections, with carbon tetrachloride the second choice.

3. Antimony and potassium tartrate is the drug of choice in blood fluke infections, although other antimony compounds have been found satisfactory in these diseases. Except possibly in fascioliasis, emetine hydrochloride has not been demonstrated to be a satisfactory drug in helminthic diseases.

4. Ethyl chloride is the drug of choice for local use in patients suffering from creeping eruption.

5. No anthelmintic is completely nontoxic for the patient in therapeutic doses. Certain drugs are more efficient and at the same time less toxic than others. Before prescribing anthelmintic treatment the physician should be sure of his diagnosis, should be familiar with the several aspects of the infection and should have clearly in mind the relative efficiencies and toxicities of the anthelmintics available for use.

8. Africa, C. M.; Garcia, E. Y., and de Leon, W.: Intestinal Heterophydiasis with Cardiac Involvement, Philippine J. Pub. Health 2: 1, 1937.

with improvement of the blood picture, symptomatic improvement has occurred, as manifested by increased appetite, gain in weight, disappearance in bone pains and subsidence of all gastro-intestinal disturbances.

The case is of moment, since it has occurred in an industry in which I can find no previous record of zinc intoxication.

## Clinical Notes, Suggestions and New Instruments

### ALUMINUM PASTE AND SKIN PROTECTION IN ENTEROSTOMY

SAMUEL McLANAHAN, M.D., BALTIMORE

The striking differentiations between various epithelial surfaces are well illustrated when intestinal contents are permitted to drain on the skin of the abdominal wall. Substances that are innocuous to the epithelium of the intestinal tract and that are even produced by it may prove most irritating and destructive to the cutaneous epithelium. This physiologic fact produces at once a clinical problem, and this problem has already been dealt with in many practical ways.

Ingenious methods of managing high intestinal fistulas have been devised, depending for their success on the twofold principle of neutralizing the alkaline secretion and of supplying some sort of protein from without the body on which the enzymes may act, thereby preserving the patient's own tissues from digestion.<sup>1</sup> In addition, suction and the application of dry kaolin have been used with great success.<sup>2</sup>

The more common problem, however, is the one presented by an ileostomy or colostomy. Here digestion per se may not be taking place, but a continuing irritation of the abdominal skin, caused probably by small amounts of trypsin, may cause the patient great physical distress. This, coupled with the mental agony occasioned by the realization, especially in the early stages, of the presence of an artificial anus, is enough to make many an individual utterly miserable. While it is quite true that many patients will have a minimal amount of irritation, still others will have a great deal, and any surgeon who has cared for such patients must necessarily have given much thought and attention to this matter of skin protection.

Seeking for a compound which when spread on the skin would form a protecting coat "heavy" enough to stick and which at the same time would be nonirritating and antiseptic, Dr. Harvey B. Stone began many years ago using an aluminum paste. The use of this paste for skin protection has extended to many of the Baltimore hospitals, where it has been employed for years with the greatest satisfaction to doctor, nurse and patient. No claim is made herewith for originality in either the composition of the paste or in its use. Indeed, I have been unable to determine the exact origin of the formula. However, a strong claim is made that there is presented here a simple medicament which has fulfilled its function of mechanical skin protection admirably through a long clinical trial.

The formula for the aluminum paste is as follows:

R Aluminum metal (fine powder).....	1 part
Liquid petrolatum (or olive oil).....	q. s. to stiff paste
Zinc oxide ointment .....	2 parts

Sometimes the preparation is used with less of the metal, the proportions being one part of the metal to three parts of the zinc oxide ointment, and this has proved satisfactory to those who have employed it. The paste may be kept in jars, and in some hospitals is kept as a routine on the dressing carriages. At other times it may be advisable to maintain a supply at the bedside of the patient who is using it. It is well to start applying the paste before there is irritation, employing it at the time the drainage is expected to commence—as when the colostomy or ileostomy is about to be opened. There is no reason, however, not to apply it to skin already irritated, and indeed in

such instances it is appreciated the most. Where there is profuse drainage, it may be necessary to apply the ointment quite frequently, sometimes with each change of dressing, to insure that the skin is adequately covered. Removal of any soiled excess of the paste may be facilitated by the use of olive oil on gauze or cotton pledgets.

The paste has also been found to be of value in protecting the skin from drainage arising from other types of fistulas. Thus it has been helpful in instances of profuse biliary discharge in which irritation has been marked, and also in suprapubic urinary fistulas.

### A NEW TYPE OF MOVABLE INFANT ISOLATION UNIT

LOUISE W. RAUH, M.D., AND J. VICTOR GREENEBAUM, M.D.  
CINCINNATI

The need for cubicle isolation of infants is universally admitted. Not every nursery, however, lends itself to installation of fixed infant cubicles owing to the arrangement of windows, radiators, doors and the like. This was the situation in the nursery in the Children's Ward of the Jewish Hospital of Cincinnati.

In order to obviate the difficulties presented by the permanent structures of the nursery, one of us (L. R.) conceived the idea of the construction of a movable, single isolation unit. A most efficient unit was constructed for us by a local firm<sup>1</sup> with the dimensions given in the accompanying tabulation.

It may be noted from the illustration that there are individual brakes on each of the wheels. The wheels can be swung to place the cubicle in any part of the room desired. The shelf in the corner of the cubicle and the board under the crib provide space for all articles used in the nursing care of the baby for twenty-four hours.

The nurses have found this unit of great value in that the isolation technic in infant care is more efficiently carried out

Movable infant isolation unit.

#### Dimensions of Isolation Unit

Height in arch in front.....	74	inches over all
Height in back.....	68½	inches over all
Length .....	54½	inches over all
Width .....	38½	inches over all
Height between floor and bottom angle	12	inches
18 gage sheet steel		
4 hard rubber wheels with brake adjustment		
1 aluminum shelf in rear left hand corner		
Constructed of 1½ by ½ inch angle iron		
Fitted with the following glass:		
2 lights 28½ by 53½ plate glass		
1 light 28½ by 28½ plate glass		

entirely within the cubicle. Up to the present the results of this technic in the use of three units have been excellent and no cross infections have occurred.

## IS CANCER A VIRUS DISEASE?

When Pasteur established the germ causation of disease, he opened a path by which hundreds of baffling diseases could be explained as an invasion of the body by microbic parasites. Specific prophylactic or immunologic therapy soon followed. Naturally, similar etiology was early suspected for cancer. Many organisms of various kinds were isolated. One heard of cancer houses, cancer regions, cancer epidemics. Many physicians still believe that cancer is due to some as yet unidentified bacterium, ameba or fungus. Years were required to disprove the idea that some micro-organism of the ordinary sort is the cause of cancer. There has persisted, however, one set of facts, repeatedly confirmed and established, which keeps alive the infective hypothesis; i. e., spontaneous malignant tumors occur in fowls, apparently due to agents that have the character of viruses. The Rous chicken sarcoma, named after its discoverer, Peyton Rous, was first reported in 1910. Much information about viruses has accumulated since then; some believe that they are chemical in nature while others hold that they are tiny living organisms resembling bacteria in serologic and other properties but too small to be seen with even the highest powered microscope. They are certainly the cause of a large group of diseases, infectious in nature, which are called virus diseases.

Now, twenty-five years after the establishment of the chicken tumors as virus diseases, a mammalian tumor has been discovered which is not only caused by a virus but not infrequently becomes a genuine cancer. Thus the relation between virus diseases and cancer becomes closer. For many years hunters in Kansas, Iowa and Texas have observed that cottontail rabbits often carry warty growths on the skin. Several years ago, Shope<sup>1</sup> showed that these growths are due to a small virus. The wart-like growths have the morphology of benign papillomas and resemble certain papillomas of dogs and cattle.

1. Shope, R. E., and Hurst, E. W.: Infectious Papillomatosis of Rabbits, *J. Exper. Med.* 58: 607 (Nov.) 1933.

Rous and Beard<sup>2</sup> undertook the study of the rabbit papilloma and showed that it had tumor characters. They were able to correlate many of their observations with the earlier ones on chicken sarcomas. More significant, however, was the fact that many of the virus-induced papillomas, experimentally engendered in domestic rabbits, became in the course of a few months true malignant squamous cell carcinomas, metastasizing and with morphologic and clinical features identical with similar tumors seen in the human being. The more active the virus, the sooner and oftener did the change from papilloma to cancer occur. These observations were promising, indeed, and the trail became truly exciting. The next step to be undertaken was, of course, the recovery from these cancers of the virus that induced the original papillomas. Despite the fact, however, that the virus could not be recovered from these cancerous growths, though vigorously growing, evidence was obtained that they were present in increasing amounts, as shown by serologic tests and by other indirect observations, even when the growths were transplanted to new hosts. The virus behaves thus differently from the various carcinogenic chemicals, such as dibenzanthracene; these substances, although present in the original tumor, disappear completely after a few transplantations.<sup>3</sup>

Rous and Kidd<sup>4</sup> have continued the attack on this intriguing problem from various angles; recently they have reported that when the virus is injected into the blood stream of rabbits with tarred ears it localizes in these organs and causes both papillomas and cancers to develop at once. Many other suggestive facts give promise that the riddle of the rôle of the virus may soon be solved. In a paper on the virus tumors and the tumor problem in a recent issue of the *American Journal of Cancer*, Rous<sup>5</sup> has assembled and discussed the evidence on the relation of viruses to neoplasms in general. Meanwhile more is being learned of virus capabilities. Investigators are now beginning to realize, through studies of herpes and certain other virus diseases, that the healthy body may harbor a virus population comparable with the many bacteria teeming within the alimentary tract and elsewhere. Unlike bacteria, which really have to live outside the cells in various crevices and along the body surfaces, viruses are protected by the cells they infect. Wherever cells exist, a virus may live; it is the elucidation of this peculiar symbiotic relationship that is the great stumbling block to further advance.

There is still a great gap between neoplasms that occur in animals and the tumors that grow in man

*Emetine Hydrochloride* ( $C_{29}H_{40}O_4N_2 \cdot 2HCl$ ), U. S. P.—This drug is prepared either from ipecac or synthetically. It is a white crystalline powder, which is freely soluble in water and alcohol. It is irritating to the skin and mucous membranes, causes nausea, vomiting and frequently diarrhea when taken by mouth, and when given intramuscularly or by vein may produce marked irritation of the gastro-intestinal tract. It inhibits digestion of starch, although it increases the tone of the nonstriated muscle of the gastro-intestinal tract. It depresses the action of cardiac muscle, causes a fall of about 20 mm. of mercury in blood pressure, and produces an irregular, weak, rapid, compressible pulse. According to Chopra,<sup>1</sup> small doses increase the secretion of the respiratory passages, with slight relaxation of the musculature; excessive doses produce pulmonary congestion. The drug is rapidly absorbed from the tissues and is excreted from the intestinal tract and kidneys. It is a general protoplasmic poison and acts particularly on the protoplasm of muscle fibers, especially of the cardiac and skeletal muscles. When administered intramuscularly or subcutaneously the dose should not exceed 0.06 Gm. daily for twelve consecutive days. A month should elapse before a second course of treatment is given. Excess use of the drug results in myocardial degeneration, which may not become manifest for many months after treatment. Khouri and Basnuovo (1935) claim beneficial results in *Fasciola hepatica* infection after the administration of 0.03 Gm. daily for from seventeen to eighteen days. Its value in pulmonary distomiasis (paragonimiasis) has not been satisfactorily demonstrated. The drug is advocated by some physicians for use in patients with blood fluke infections when antimony compounds are poorly tolerated.

*Ethyl Chloride*. (monochlorethane,  $C_2H_5Cl$ ), U. S. P.—Under pressure, ethyl chloride is a colorless, volatile inflammable liquid with an ethereal odor. Its usefulness has been amply proved in cases of "creeping eruption" due to infective stage larvae of hookworms migrating in the cutaneous layers (Kirby-Smith, 1935). When it is sprayed on the parasitized skin in sufficient amounts to insure temporary freezing of the involved area, the larvae are killed and are later phagocytosed and absorbed.

#### IMPORTANT HELMINTHIC DISEASES

In considering helminthic diseases it is desirable to include (1) those commonly observed in the United States and (2) those common in other parts of the world which both are clinically important and are sufficiently prevalent as to constitute a public health problem. In the first group hookworm infection and ascariasis are conspicuous; in the second category diseases such as schistosomiasis deserve consideration.

#### HOOKWORM INFECTION

Hookworm infection in man is produced by three separate species of hookworms: (1) *Necator americanus*, which is almost the only species in the United States and is the prevalent form in Central and South America, Central and South Africa, southern Asia, Polynesia and Micronesia; (2) *Ancylostoma duodenale*, the species of Europe, northern Africa and the prevalent form in northern Asia, and (3) *A. braziliense*, a species with "spotted distribution" in tropical and subtropical areas of the world. The former two species are almost exclusively human parasites; *A. braziliense* is more commonly found in dogs and cats than in man.

The adult males and females, which are about the size of a small pin, live attached typically to the wall of the middle third of the small intestine. The females each lay a few thousand eggs daily. The eggs, which are evacuated in the stools, become fully embryonated and hatch when they are deposited on warm moist humus in a shady location. The larvae feed on organic debris, grow and metamorphose in the soil and in nine days or more become infective for man, usually entering the human body through the skin of the feet, less commonly on other exposed parts of the body. From the skin they migrate through the lungs to the digestive tract, where they grow into adult worms, become attached to the intestinal wall and repeat the life cycle. At the sites of attachment to the intestine the worms produce nonhealing lesions and withdraw blood from the intestinal capillaries. A few worms cause little symptomatology; many hundreds or thousands produce hookworm disease, which modern experimental and clinical studies attribute primarily to loss of blood, with a picture of microcytic hypochromic anemia. This drain on the erythropoietic system constitutes the background for the classic hookworm syndrome of "laziness," toxic edema and emaciation, dry skin, indigestion and delayed puberty so characteristic of a severe infection. Frequently the infection is complicated by or is superimposed on a state of malnutrition. Specific diagnosis consists in the recovery and identification of the eggs of the parasite from the patient's feces, either in unconcentrated films or after centrifugation or brine flotation of a stool specimen.

In severe cases it is desirable to build up the patient by transfusions or administration of iron and liver before specific therapeutics is instituted. In hookworm infection uncomplicated by ascariasis, tetrachlorethylene is the drug of choice (3 cc. for an adult, 3 minims per year of age for children). When *Ascaris* is also present hexylresorcinol may be used (1 Gm. in gelatin capsules for persons over 10 years of age, from 0.2 to 0.8 Gm. for smaller children) to remove from 90 to 100 per cent of *Ascaris* and 75 to 85 per cent of the hookworms. Treatment with hexylresorcinol may safely be repeated once a week to kill the remaining hookworms. Pretreatment and post-treatment purgation, preferably with sodium sulfate (Glauber's salt) is desirable to clean off excess mucus from the intestinal wall and to increase peristalsis. A light (i. e., subclinical) hookworm infection, which may be diagnosed by the scarcity or absence of eggs in three consecutive unconcentrated films, should be distinguished from hookworm disease, in which the number of worms in the intestine is sufficient to produce symptoms. Instruction should be given to the patient and his relatives regarding the preventive aspect of hookworm infection.

*A. braziliense* in the southern part of the United States rarely develops into the adult intestinal stage. On entering the skin the larvae usually produce "creeping eruption," migrating for considerable distances in serpiginous tunnels through the cutaneous tissues. This clinical entity is particularly prevalent along the South Atlantic and Gulf coasts. For it ethyl chloride spray is indicated.<sup>7</sup>

#### ASCARIASIS

Ascariasis is produced by the large intestinal roundworm, *Ascaris lumbricoides*, which is usually creamy yellow or creamy pink and approximately the size of a

<sup>7</sup> Kirby-Smith, J. L.: The Treatment of Creeping Eruption, South. M. J. 28: 999 (Nov.) 1935.

of the amount of vitamin C stored by these subjects at saturation gave values of approximately 2,500 to 3,000 mg. These suggestive calculations are supported by other data in the literature and supply an interesting answer to the important question of the capacity of the tissues to store vitamin C. Furthermore, it appears that the clinical practice of providing large quantities of orange juice for patients with suspected or outspoken scurvy has definite support from this experimental study.

## Current Comment

### THE VITAMIN C CONTENT OF ORANGE JUICE

In newspapers and magazines, on car cards and billboards the public is being told by the California Fruit Growers Exchange that Sunkist navel oranges are "22 per cent richer in vitamin C." What evidence exists for this statement and what significance should be attached to it? Last September, among other papers presented at the meeting of the American Chemical Society in Pittsburgh, was a report by A. J. Lorenz of the California Fruit Growers Exchange. His paper bore the imposing title "Statistical Review of 1,100 Sugar-Ratio Determinations Correlated with Vitamin C Values Representing 14,000 Oranges under Varying Conditions." The juice of California oranges was reported to contain an average of 0.60 mg. of cevitamic acid per cubic centimeter, whereas the juice of Florida oranges contained 0.53 mg. when tested by the same chemical method. The difference is only 13 per cent, so perhaps the California organization did not use its own values as a basis for the claim of superior vitamin C content. A recent report from the laboratory of the Bureau of Home Economics of the United States Department of Agriculture contains data of interest.<sup>1</sup> The Washington investigators determined the cevitamic acid content of the juice of fresh valencia and navel oranges grown in California and of valencia and pineapple oranges grown in Florida. The cevitamic acid in milligrams per cubic centimeter of orange juice for each of these four varieties was found to be respectively 0.40, 0.58, 0.45 and 0.51. There appears to be no justification, therefore, in this unbiased report to a claim that the oranges grown in California provide 22 per cent more vitamin C than do Florida oranges, because the variety of orange, as well as the locality in which it is grown, must be considered. It is the opinion of the government investigators that the volume of juice per orange is also a factor worthy of consideration. The California navel orange yields less juice than do other varieties of the orange of equal size. Of greater importance is the application of the laboratory observations to problems of nutrition. When the vitamin C content is translated to international units (one international unit is equivalent to 0.05 mg. of cevitamic acid) the point is brought out that fresh orange juice contains approximately 1,000 units per hundred cubic centimeters. This volume is roughly  $3\frac{1}{2}$  fluidounces, or somewhat less

than one-half cup in terms of ordinary household measures. The relatively slight differences in vitamin C content of different varieties of fresh oranges amounts to about a tablespoonful more or less of juice added or subtracted from this volume. It is generally recognized that the minimum amount of vitamin C required to prevent scurvy in man is about 300 international units. A desirable intake for an adult would be more than the estimated minimum requirements, of course, and different authorities have suggested values of from 500 to 1,000 units. It is apparent that all four varieties of the orange are excellent sources of vitamin C. To direct attention to slight differences in vitamin C content with the view of capitalizing them is both misleading and contrary to the interests of the public. Such unfortunate publicity tends to defeat the efforts of nutritionists and physicians to educate the public about the importance of the various fruits and other foods that go to make up our diet. It does not reflect credit on the large California Fruit Growers Exchange.

### AUTOMOBILE TRAILER SANITATION

As trailers multiply on our roads, new sanitary problems arise to disturb our health officials. Foremost are the provision of safe milk and water and the sanitary disposal of human waste.<sup>1</sup> With reasonable care in choice, safe water is readily available along the highways in many states; similarly the obtaining of safe milk, while slightly more difficult, offers no great hazard to the careful purchaser. The chief source of concern is the unsafe or insanitary disposal of human excreta by trailer travelers. Many trailers now provide a small toilet compartment in which excreta may be deposited in cans containing chemical solutions reputed to render the waste innocuous. What to do with the material in the cans is the problem of present concern. No extensive or satisfactory sanitary provisions have been made for the disposal of these wastes and the cleansing of the cans. Serious consideration, it is believed, must now be given to providing roadside facilities for the sanitary disposal of human waste from auto trailers. State or county departments of health may construct disposal systems near roads frequented by auto trailers, the location of which can be made known by appropriate road signs. Recognition has been recently accorded the problem by the city and county of San Francisco,<sup>2</sup> which has prepared a sanitary code suggested for their citizens when using such conveyances for traveling. According to this code, all trailers should be equipped with an air-tight container of not less than five gallons capacity for the storage of garbage. This container may be emptied only in places approved and so designated by the health authorities of a particular locality. If the trailer is equipped with running water and a flush toilet, an adequate sewage tank should be provided underneath the trailer for the collection and storage of such waste. The tank should be emptied only into sewer connections or by other approved methods of disposal provided by the community. When equipped with water tanks for household use, the tanks must be

a progeny that eventually becomes infective for man by the skin route. The migration through man's tissues parallels that of the hookworms. Strongyloidiasis is a chronic insidious infection, frequently without dramatic symptoms. At times, however, there is a persistent watery or mucous diarrhea due to extensive irritation and desquamation of the intestinal mucosa, systemic toxemia and nervous symptoms, anemia, emaciation, debility and complete exhaustion. At times internal reinfection is believed to occur. The mother worms may also colonize the respiratory epithelium. Diagnosis is based on recovery of the motile larvae in the stools. Only one chemotherapeutic, gentian violet medicinal, has been found to be specific for this infection. When administered in enteric-coated tablets (0.06 Gm. three times a day for sixteen and two-thirds days) immediately before meals, it is usually well tolerated and frequently eradicates the organism. At times two or three courses of treatment are necessary to effect a cure; less commonly cure cannot be secured by this method and intubation of 25 cc. of a 1 per cent solution of the dye into the duodenum is indicated. A satisfactory technic for treating pulmonary strongyloidiasis has not been developed. Prevention follows essentially the same lines that have been devised for hookworm infection.

#### TAPEWORM INFECTIONS

Human intestinal tapeworm infections include those produced by *Taenia saginata* (beef tapeworm), *T. solium* (pork tapeworm), *Diphyllobothrium latum* (broad fish tapeworm), *Hymenolepis nana* (dwarf tapeworm) and *Hymenolepis diminuta* (rat tapeworm). Other species of tapeworms recovered from man's intestine are relatively unimportant because of their infrequent occurrence. *Echinococcus granulosus*, the cystic larval stage of which produces hydatid disease in man and mammals, is a somatic infection which is not amenable to chemotherapy. The eggs of all intestinal tapeworms are evacuated in the feces. *Taenia saginata* and *T. solium* require as an intermediate host respectively the ox and the pig. The raw flesh of these animals, containing the mature larval stage, produces infection in man. The broad fish tapeworm requires two larval hosts, (1) a cyclops and (2) later a fresh-water fish. Ingestion of the uncooked flesh of the infected fish is responsible for human infection. *Hymenolepis nana* requires no intermediate host; the eggs evacuated in human feces are directly infective for man. *Hymenolepis diminuta* requires an insect or other arthropod intermediate host, the accidental ingestion of which causes infection in man. With the exception of *Diphyllobothrium latum*, which is conspicuously prevalent in the north temperate and subarctic regions, all these infections have a more or less cosmopolitan distribution, although they are correlated with certain food preferences of a population or with lack of personal or group hygiene. *Hymenolepis nana* is more common in children than in adults.

All tapeworm infections provoke essentially the same type of symptoms, which vary in amount depending primarily on the mass of the infection (i. e., worm burden) and the individual susceptibility to absorbed toxins. These symptoms include indigestion, loss of weight, false hunger pains, insomnia, nervous reflexes and other evidences of systemic toxemia. At times, as in *Diphyllobothrium latum* infection, a severe secondary anemia may be produced. The infections are all

detected by identification of the eggs or "segments" of the worm discharged in the feces. The most reliable drug for all tapeworm infections is probably oleoresin of aspidium. The night before treatment a sodium sulfate purge should be administered. On the morning of treatment the patient should remain in bed, should refrain from taking food, and should take the drug in capsules, preferably in three divided doses of from 10 to 20 minims each (total 30 to 60 minims for adults, 2 minims each per year of age for children) at half-hour intervals. Two hours after the last dose a post-treatment sodium sulfate purge should be administered. No food should be taken until after a copious bowel movement has been effected. Stools should be saved and examined up to twenty-four hours for the heads of the worms. On account of the toxicity of the drug (see precautions and contraindications under "Oleoresin of Aspidium"), a second treatment should not be given within one week. For small children or adults who become severely nauseated by the drug, administration may be by intubation into the duodenum. In case of *Taenia* infections, Maplestone and Mukerji (1931) recommend carbon tetrachloride, as administered for hookworm infection. Hexylresorcinol, as prescribed for ascariasis, is fairly efficient in removing *Hymenolepis nana* from the intestine and is probably the drug of choice for small children harboring this worm, since its toxicity is very slight and repeated treatments may be given within a relatively short time. Prevention of tapeworm disease depends on the source of infective material, whether animal flesh consumed by man, accidental ingestion of arthropod intermediate hosts or direct ingestion of eggs.

#### BLOOD FLUKE INFECTIONS (SCHISTOSOMIASIS)

Three species of blood flukes, *Schistosoma haematobium*, *S. mansoni* and *S. japonicum*, parasitize large groups of the human population, in whom they invariably produce serious clinical manifestations. *S. haematobium*, causing vesical schistosomiasis, is prevalent in Egypt, many other parts of Africa and regions of Asia west of the Indus River. It has also been discovered endemically in southern Portugal. *S. mansoni*, causing intestinal schistosomiasis, is common through extensive areas of Africa and is prevalent in northern Brazil, Venezuela, Dutch Guiana, the Lesser Antilles and Puerto Rico. *S. japonicum* is found in a few foci in Japan, in extensive areas in central and southern China, in Formosa and in at least one locality (Leyte) in the Philippines. These worms reside in the vesical and pelvic plexuses of the venous blood stream (*S. haematobium*) and the intestinal venules and portal system (*S. mansoni*, *S. japonicum*), where they lay their eggs, some of which work their way through the tissues and are discharged in the urine (*S. haematobium*) or feces (*S. mansoni*, *S. japonicum*). The eggs hatch in water and the escaping larvae enter the appropriate species of snail and undergo a metamorphosis and twofold multiplication. A second larval stage (cercariae) eventually erupts from the snail. This free-swimming stage is infective for man, typically through the skin. After a circuitous journey through the lungs and systemic circulation the young worms accumulate in the portal blood system, grow and then migrate against the venous blood flow to the sites of their predilection (i. e., vesical or mesenteric veins and their tributaries). The juvenile and adult worms are responsible for the toxic symptoms; the eggs which they discharge produce local

the meaning of this act," and (5) to authorize imprisonment in the county jail for from two to six months for narcotic addicts and to forbid probation to or the staying of execution of the sentence imposed on a convicted narcotic addict. A. 181, to amend the state retail sales tax act of 1933, proposes to exempt from the provisions of the act "the gross receipts from sales of all medicines and preparations recognized in the United States Pharmacopeia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation or prevention of disease of either man or other animals." A. 384 and A. 385, to supplement the workmen's compensation act, propose that all records of any hospital, physician or other person or institution with respect to services rendered to any injured workman, including but not restricted to x-rays and histories of injuries and diagnoses, shall be exhibited to the patient and to any person authorized in writing by him to examine the same. The patient or his authorized agent must be permitted to make copies of such records.

### CONNECTICUT

**Bill Introduced.**—H. 32 proposes to exempt from taxation "one vehicle owned by a practicing physician or surgeon and used by him in the practice of his profession."

### DISTRICT OF COLUMBIA

**Medical Bills in Congress.**—*Bills Introduced:* S. 989, introduced by Senator Copeland, New York, and H. R. 3352, introduced by Representative Mitchell, Illinois, propose to provide for the issuance of a license to practice the healing art in the District of Columbia to Dr. Clarence Quinton Pair.

### GEORGIA

**Chevalier Jackson to Give Memorial Lecture.**—Dr. Chevalier Jackson, professor of clinical bronchoscopy and esophagoscopy, Temple University School of Medicine, will deliver the Jonte Eguen Memorial Lecture of the Fulton County Medical Society, February 11. His subject will be "Pulmonary Abscess in Adults and Children, Based on a Series of Clinical Observations."

**Bills Introduced.**—H. 7, to amend the dental practice act, proposes to authorize the revocation of a practitioner's license, among other things, for "unprofessional dental conduct," which the bill states "shall mean gross indecency, or gross uncleanness, or habitual intemperance or addiction to drugs to such an extent as to make him unsafe to render dental services; or employing directly or indirectly any suspended or unlicensed dentist to perform dental operations; or soliciting dental business directly or indirectly, by himself or through an agent, by the use of cards, letters, circulars, publications, pictures, radio, display or signs." S. 32 and H. 37 propose to require all applicants for licenses to practice any form of the healing art, as a condition precedent to examination by their respective professional boards, to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology before a state board of examiners in the basic sciences, no member of which is to be actively engaged in the practice of the healing art or any branch thereof. H. Res. 11-41B proposes so to amend the state constitution as to permit any county to levy a tax to provide medical care and hospitalization for the indigent sick of the county. H. 12 proposes to establish a board of naturopathic examiners and to regulate the practice of naturopathy defined as "a system of treating the human body by use of drugless methods and shall include the following therapeutic measures: mechanotherapy, hydrotherapy, psychotherapy, phytotherapy, phototherapy, therotherapy [sic], electrotherapy, and embracing such practices as manipulation and massage, mineral, thermal, electric and vapor baths, external applications and dietetics." The bill proposes to license without examination all persons who have been engaged in the practice of naturopathy in the state for one year or more prior to the approval of the bill. All other applicants for licenses must be high school graduates or have completed equivalent courses of study and have studied naturopathy for four years of nine months each in a school of naturopathy approved by the board of examiners, and pass examinations to be given by the board in anatomy, physiology, chemistry, pathology, histology, bacteriology, massage, therapeutics, diagnosis and treatment and such added subjects as may subsequently be taught by accredited schools of naturopathy. H. 35 authorizes the sexual sterilization of certain socially inadequate inmates of state institutions.

### ILLINOIS

**Appointments to Medical Examining Committee.**—Dr. Milton M. Portis, Chicago, has been appointed a member of the professional committee for medicine in the Illinois State Department of Registration and Education, to fill the vacancy caused by the death of Dr. Gilbert FitzPatrick. Dr. William L. Karcher, Freeport, was appointed to succeed the late Dr. Malcolm L. Harris, Chicago. Dr. Portis, a graduate of Rush Medical College, was formerly clinical professor of medicine at Loyola University School of Medicine. Dr. Karcher graduated from the Medico-Chirurgical College of Philadelphia in 1900. Other members of the committee are Drs. John R. Neal, Springfield, secretary, and Arthur H. Geiger, Chicago. There is still one vacancy on the committee.

### Chicago

**Dr. Means Lectures at Thorne Hall.**—Dr. James H. Means, Jackson professor of clinical medicine, Harvard University Medical School, Boston, will address the North Side Branch of the Chicago Medical Society in Thorne Hall, on McKinlock Campus, Northwestern University, February 4, at 8 o'clock. His paper is entitled "The Role of the Physician in the Management of the Patient with Thyrotoxicosis."

**Dr. Kreuscher Named Surgeon of Steel Company.**—Dr. Philip H. Kreuscher, assistant professor of surgery, Northwestern University Medical School, has been appointed chief surgeon of the Carnegie-Illinois Steel Corporation in the Chicago area. He succeeds Dr. George C. Davis, resigned. Dr. Kreuscher graduated from Northwestern in 1909 and has been teaching there since 1915. He was formerly medical director of the Illinois Industrial Commission and in 1933 was president of the Illinois State Medical Society.

**Society News.**—The Chicago Roentgen Society was addressed, January 14, by Drs. Bernard H. Nichols, Cleveland, on "Significance of Anomalies of the Kidney and Ureter," and Jacob Sagel, Gary, Ind., "Ewing's Tumor of the Femur."—Dr. Arthur J. Bedell, Albany, N. Y., addressed the annual meeting of the Chicago Ophthalmological Society, January 18, on "The Ophthalmoscopic Signs of Failing Health."—At a meeting of the Chicago Society of Allergy, January 18, Dr. Francis L. Foran, among others, discussed "Treatment of Hay Fever with a Modified Pollen Solution."—The Chicago Pediatric Society was addressed, January 19, among others, by Dr. Frederic W. Schlutz on "Treatment of Nephrosis in the Young Child."

### KANSAS

**Bills Introduced.**—H. 66 proposes to establish a state registration and examining board for medical technicians, to regulate the carrying on of "the occupation which includes bacteriology, serology, hematology, microbiology, parasitology, and biochemistry," and to make it unlawful for any person to operate or engage in clinical laboratory work unless first licensed by the board. Registered medical technicians are to be classed as either senior or junior medical technicians. A senior medical technician must be a graduate of an accredited college or university with a minimum degree of bachelor of arts or science and must have had three years' experience in a laboratory acceptable to the board, while a junior technician need only be a graduate of an accredited high school and have had one year training or experience acceptable to the board. A senior medical technician is to have the right to supervise or direct a clinical laboratory, while a junior technician can practice only under the direction of a senior technician. H. 75 proposes to make it the duty of every physician to report to the state board of health within forty-eight hours after knowledge of the facts the name of every person he knows to be afflicted with syphilis. The state board of health is then to be authorized to require such reported person to appear before it and, if the board finds the person to be afflicted with syphilis, it is its duty to order such person, if a female under 45 or a male under 65, to be sterilized.

### KENTUCKY

**Personal.**—Dr. Jacob L. Tanner, Henderson, was elected president of the Green River Valley Public Health Association at a meeting December 31 in Madisonville, and Dr. James O. Nall, Cadiz, vice president.—Dr. Herbert H. Hunt, Mayfield, has been appointed health officer of Graves County, succeeding Dr. John R. Pryor.—Dr. Ernest L. Gates, Greenville, has recently been appointed a member of the state board of health.

**Society News.**—At a joint meeting of the medical societies of Carlisle, Hickman and Ballard counties at Bardwell, December 1, the speakers were Drs. George Ezra Tinsworth Jr., Bandana, on "Differential Diagnosis of Tuberculosis from a

## Council on Physical Therapy

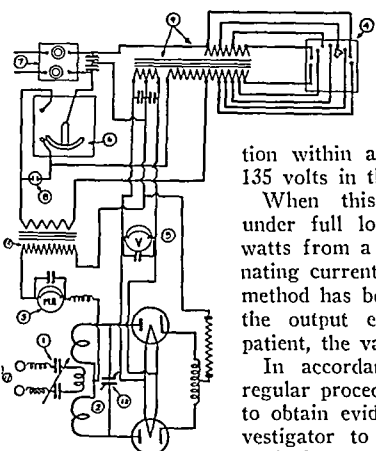

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

### PEERLESS SHORT WAVE UNIT, MODEL SWP-5, ACCEPTABLE

Manufacturer: Peerless Laboratories, Inc., New York.  
The Peerless Short Wave Unit, Model SWP-5, is recommended for medical diathermy and minor electrosurgery. The attachments for tissue cutting, coagulation and desiccation are part of the equipment. Pad and cuff electrodes are supplied with the set.

The apparatus is a two tube self-excited, push-pull oscillator operating at 14 meters. The patient circuit is inductively and capacitatively coupled to the oscillator circuit. The tuning of the patient is accomplished by means of a double condenser (with plates moving parallel), which tunes the two branches of the patient circuit simultaneously.

For consistency of performance and maximum life to tubes and other component parts, a switching arrangement is incorporated in the machine

Peerless Short Wave Unit, Model SWP-5

which enables the physician to adjust the operating voltages on filament, grid and plate to line voltage variation within a range of from 105 to 135 volts in the power supply line.  
When this machine is operated under full load, it draws about 650 watts from a 60 cycle 115 volt alternating current line. Since no reliable method has been proposed to measure the output energy available to the patient, the value is not given.  
In accordance with the Council's regular procedure, the firm was asked to obtain evidence from a reliable investigator to substantiate the claims made for the unit.  
Subjects for the test were two vigorous male students weighing 174 and 180 pounds and were 24 and 27 years of age. Six observations were made. Two trocars placed in hard rubber cannulas were inserted into the thigh. One was introduced midway between Poupart's ligament and the knee and straight down into the depth of the muscular tissue until the instrument was at an approximate depth of 2 inches, or until the femur was encountered. The second was introduced as nearly parallel to the skin as possible and subcutaneously at an approximate depth of one-eighth inch. The trocars were removed, leaving the rubber cannulas in situ. Temperature measurements were then taken by means of thermocouples of the hypodermic needle type and introduced through the cannulas. The constant junction was immersed in ice, enclosed in a quart vacuum bottle.

#### Average of Six Observations with Cuff Electrodes

Deep Muscle Temp. F.		Subcutaneous Temp. F.		Oral Temp. F.	
Initial	Final	Initial	Final	Initial	Final
99.7	103.4	98.7	102.4	98.8	99.0

The electromotive force due to the difference in temperature of the junctions was read in millivolts from a Leeds and Northrup portable potentiometer. The thermocouples were calibrated in degrees Fahrenheit, against a Bureau of Standards certified thermometer. Initial temperatures were taken and then the subject was subjected to a twenty minute application of maximum current intensity consistent with skin comfort. At the end of this period, temperatures were again recorded until the temperature began to drop. The highest temperature attained was recorded as the final temperature in each instance. Oral temperatures were also recorded.

Rubber pad electrodes measuring  $2\frac{1}{2}$  by  $23\frac{1}{2}$  inches were employed as cuffs, one above and one below cannulas inserted in the thigh; three-eighths inch thickness of orthopedic felt with two layers of towel between the skin surface and the electrodes. Cannulas were placed midway between the cuff electrodes.

Each reading in the table is an average of six observations. The temperature rise of the transformer, after the machine had been operated at full load for two hours, came within the limits of safety prescribed by the Council. The shipping weight of the unit is about 100 pounds. Burns may be produced but may be avoided by ordinary precaution. Their likelihood to occur is less than with conventional diathermy, employing metal electrodes.

The Peerless Short Wave Unit, Model SWP-5, was tried out in a clinic acceptable to the Council and found to be satisfactory. No claims are made for its use in fever therapy.

In view of the favorable report based on the performance of this unit when cuff electrodes were applied, the Council on Physical Therapy voted to include the Peerless Short Wave Unit, Model SWP-5, in its list of accepted devices.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

**CRYSTAL VIOLET.**—Hexamethyltri-amino-triphenylmethane.—Hexamethylpararosaniline chloride.— $(\text{CH}_3)_2\text{N.C}_6\text{H}_4.\text{C}:\text{C}_6\text{H}_4:\text{N}:(\text{CH}_3)_2\text{C}_6\text{H}_4$ .

**Actions and Uses.**—See general article "The Triphenylmethane (Rosaniline) Dyes," New and Nonofficial Remedies, 1936, p. 199.

**Dosage.**—For direct application, a solution of from 1 in 500 to 1 in 1,000 may be employed. For the treatment of burns, local applications in the form of a spray or jelly containing 1 per cent of crystal violet have been employed.

Crystal violet occurs as a dark green amorphous powder having a light metallic luster. It is soluble in alcohol, chloroform, glycerin and water, practically insoluble in benzene and ether.

Reduce about 0.2 Gm. of crystal violet with zinc and diluted hydrochloric acid until colorless, filter through paper; no immediate coloration occurs, but a blue zone appears at point of contact when the solution is spotted with ammonia water.

When tested for arsenic according to U. S. P. XI, the product should meet the requirements for arsenic (p. 438, Arsenic Test). To about 1 Gm. of crystal violet previously ignited in a platinum dish with an excess of sulfuric acid, add 5 cc. of hydrochloric acid and evaporate to dryness, treat the residue obtained with 20 cc. of a diluted hydrochloric acid (1 part of acid and 20 parts of water), warm, filter through paper and divide into two portions: a faint precipitate occurs on saturation with hydrogen sulfide (heavy metals); no precipitation on the addition of 1 cc. of potassium ferrocyanide solution (zinc).

Dry about 1 Gm. of crystal violet, accurately weighed, to constant weight at 100 C.; the loss does not exceed 2.5 per cent. Incinerate about 1 Gm. of crystal violet, accurately weighed, previously dried at 100 C.; the ash does not exceed 1 per cent. Dissolve about 1 Gm. of crystal violet, previously dried at 100 C., in 300 cc. of alcohol; heat to boiling; collect the insoluble matter, if any, in a tared Gooch crucible; wash the insoluble matter with hot alcohol, dry the insoluble matter to constant weight at 100 C.; the insoluble matter does not exceed 0.1 per cent. Transfer about 0.5 Gm. of crystal violet to a 500 cc. Kjeldahl flask and determine the nitrogen content according to the official method described in Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists, third edition, page 20, chapter 2, paragraph 22: the percentage of nitrogen corresponds to not less than 10 per cent, nor more than 11 per cent when calculated to the dried substance. Transfer about 0.5 Gm. of crystal violet to a Parr sulfur bomb; determine the chlorine content by the Parr method: the amount of chlorine found corresponds to not less than 8.4 per cent nor more than 8.9 per cent when calculated to the dried substance. Dissolve about 5 Gm. of crystal violet, accurately weighed, in 400 cc. of water, previously boiled, cool under carbon dioxide and make up to a 500 cc. volume in a volumetric flask; transfer an aliquot of 50 cc. to a mixture of 20 cc. alcohol, 10 cc. glacial acetic acid, 50 cc. of a 20 per cent solution of potassium and sodium tartrate, and 50 cc. of water, and while continually boiling titrate with tenth-normal titanium trichloride solution: the percentage of purity (using factor 0.020386) corresponds to not less than 96 per cent nor more than 100 per cent when calculated to the dried substance.

**Crystal Violet Medicinal-Calco.**—A brand of crystal violet-N. N. R.

Manufactured by the Calco Chemical Co., Inc., Bound Brook, N. J. No U. S. patent or trademark.

**Crystal Violet Jelly-Calco.**—A 1 per cent aqueous solution of crystal violet-N. N. R. in a gum tragacanth jelly base.

a group of cooperating specialists. Three nights a week, Monday, Wednesday and Friday, will be devoted to special lectures in the center. The tuition for each week's course is \$15 for full time enrolment. An advance registration fee of \$3 should be sent with the application, which must be addressed to the director of the Center for Continuation Study, University of Minnesota, Minneapolis.

### NEW JERSEY

**Dr. Shope Awarded Medal.**—Dr. Richard Edwin Shope of the department of animal and plant pathology of the Rockefeller Institute for Medical Research, Princeton, is to receive the John Phillips Memorial Medal of the American College of Physicians for 1937. Dr. Shope is 34 years old and a graduate of the State University of Iowa School of Medicine, class of 1924. He has been associated with the Rockefeller Institute since 1925, working in the field of animal pathology, especially on the filtrable viruses. The medal will be awarded at the annual meeting of the American College of Physicians in April.

**Society News.**—The Society of Surgeons of New Jersey met in Newark, January 6. Clinics were held at the Newark Beth Israel Hospital, followed by a dinner at the Hotel Douglas. Dr. Frank G. Scammell, Trenton, was elected president. Dr. Leonard G. Rowntree, Philadelphia, addressed the Camden County Medical Society, Camden, January 5, on "Endocrinology from the Internist's Viewpoint." Dr. Samuel A. Loewenberg, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, January 8, on "Diagnosis and Treatment of the More Common Forms of Cardiac Affections." Dr. George T. Pack, New York, addressed the Bergen County Medical Society, Hackensack, December 8, on cancer and its early diagnosis. Dr. Theodore Neustaetter, New York, addressed the society, January 12, on endocrinology.

### NEW YORK

**Bills Introduced.**—S. 67 proposes to establish in the Department of Public Health a bureau of narcotic control. S. 159 proposes to limit the hours of labor of employees of private hospitals to eight consecutive hours in any twenty-four hours, not more than eight hours in any day and not more than forty-eight hours in any calendar week, except in an extraordinary emergency during an epidemic, plague or other catastrophe.

**Society News.**—Dr. George T. Pack, New York, addressed the Medical Society of the County of Westchester, White Plains, January 19, on "Diagnosis and Treatment of Cancer of the Stomach and Duodenum." Dr. James E. Sadlier, Poughkeepsie, addressed the Putnam County Medical Society, December 2, on surgery of the large intestine. Dr. John J. Morton Jr., Rochester, addressed the Ontario County Medical Society at its recent quarterly meeting at Canandaigua Lake on modern treatment of cancer.

### New York City

**Personal.**—The honorary degree of doctor of science will be conferred on Dr. Charles Gordon Heyd, President of the American Medical Association, by Temple University, Philadelphia, at its Founders' Day exercises, February 15. Dr. Victor G. Heiser sailed January 7 for a five months' tour of Africa. He will visit leper colonies and investigate the possible spread of yellow fever by airplane travel.

**Dr. Stookey to Succeed Dr. Elsberg at Neurological Institute.**—Dr. Byron Stookey, associate professor of neurological surgery at Columbia University College of Physicians and Surgeons and senior attending surgeon at the New York Neurological Institute, has been appointed chief of the neurologic service at the institute, an affiliate of Columbia. Dr. Stookey succeeds Dr. Charles A. Elsberg, who has been associated with the institute since 1909 and is also professor of neurologic surgery at Columbia. Dr. Elsberg, who is 64 years old, will retain his professorship at Columbia and will devote most of his time to research. Dr. Stookey is 50 years old and was graduated from Harvard University Medical School in 1913. In addition to his position on the faculty of Columbia he is director of neurosurgery at New York Post-Graduate Medical School and consulting neurosurgeon to various hospitals.

**Society News.**—At a meeting of the International Spanish Speaking Association of Physicians, Dentists and Pharmacists, December 18, the speakers were Drs. William T. Kennedy, on "Incontinence of Urine in the Female"; Oscar Glassman, "Hyperemesis Gravidarum," and Joseph Broadman, "The Role of the Physician in the Coming War." The New York

Academy of Medicine held its annual meeting January 7, with Hon. Thomas D. Thacher, former solicitor general of the United States, as the guest speaker on "Medicine and the State." Dr. Eugene H. Pool, retiring president, reviewed recent activities of the academy and Dr. James Alexander Miller, incoming president, made an address on "Ideals in Medicine." At a joint meeting of the section of neurology and psychiatry of the New York Academy of Medicine and the New York Neurological Society, January 12, the hypoglycemic treatment of psychoses was discussed by Drs. Manfred Sakel, Vienna, Bernard Glueck, Ossining, and Joseph Weris of Bellevue Hospital. Dr. Thomas P. Sprunt, Baltimore, addressed the Harlem Medical Association, January 6, on "The Parathyroids and Diseases of Bones." The New York Society of Tropical Medicine gave a dinner in honor of Dr. Ernest Muir, London, secretary of the British Empire Leprosy Relief Association, at the City Club, December 1.

### NORTH DAKOTA

**Bill Introduced.**—H. 21 proposes to establish a board of naturopathic examiners and to regulate the practice of naturopathy, defined as "the manipulation of the articulation of the human skeleton by hands or mechanical appliances and/or the use of any physical force such as air, water, light, heat, color, exercise, pressure, vibration, electricity, hydrotherapy, including mineral salt baths and/or any other means or system of therapeutics and didactics connected with the above therapeutic measures, including non-toxic herbs and their essential oils, gums and resins applied, administered or prescribed, but shall not include the administration of drugs or major surgery." An applicant for such a license must be over 21 years of age, have completed a course of study in an accredited high school, or its equivalent, and in addition thereto have received from an accredited legally chartered school or college of naturopathy, after a four year period of study, credits in anatomy, physiology, hygiene and sanitation, chemistry, histology, pathology, diagnosis, didactics, gynecology, obstetrics, toxicology, minor surgery, therapy and practice of naturopathy and physical therapy, electrotherapy and hydrotherapy, clinic, and such other subjects as the board may require except materia medica and major surgery. Applicants must pass examinations in the subjects just noted. The bill further provides that "naturopathic physicians shall be subject to all health laws relating to contagious diseases and birth and death certificates as now apply to other licensed physicians."

### OHIO

**Bills Introduced.**—H. 42 proposes to forbid the issuance of a marriage license until there has been filed on behalf of each party to the proposed marriage a certificate signed by a licensed physician, stating whether or not "the serological reaction of a blood test of such applicant gives a positive or negative finding of syphilis, and also a record of the standard laboratory blood tests made." If the serologic reaction of a blood test of an applicant gives a positive finding of syphilis, no license to marry can be issued. H. 45, to amend the workmen's compensation act, proposes that the term "injury" as used in the act "shall include any injury received in the course of employment." H. 54, to amend the medical practice act, proposes to require applicants for licenses to practice medicine, if they do not possess a diploma from a reputable college granting the degree of A.B., B.S. or equivalent degree, to present a certificate from an accredited college or university of arts or sciences showing that the applicant has satisfactorily completed at least two full college years in such an institution in premedical subjects.

### OKLAHOMA

**Personal.**—Dr. John A. Morrow, Sallisaw, has been appointed chairman of the committee on practice of medicine in the state house of representatives. Dr. Vester M. Rutherford, Woodward, has been appointed health officer of Woodward County.

**Bill Introduced.**—H. 126 proposes to forbid the issuance of a license to marry unless both parties to the proposed marriage are free from gonorrhea, syphilis or other venereal disease, which facts must be certified to by a licensed physician.

**State Hospital Meeting.**—Mr. R. L. Lov Jr., superintendent, Oklahoma City General Hospital, was elected president of the Oklahoma State Hospital Association at its annual meeting in Tulsa in December. Dr. Bert W. Caldwell, executive secretary of the American Hospital Association, Chicago, and Mr. Robert Jolly, Houston, Texas, former president of the American Hospital Association, were among the speakers.

Moreover, even if cancer in man proves to be a virus-induced disease it cannot be considered as being infective from person to person in the ordinary sense of the word. Repeated clinical study has not revealed any instance of such a transmission of cancer. As far as present evidence is concerned, therefore, in spite of the relation of the viruses to infection, there need be no fear of contact with cancer patients.

### STORAGE OF VITAMIN C

The development of accurate and rapid methods for the quantitative determination of vitamin C has led to extensive investigations of its biochemistry and physiology. Its solubility in water suggests the kidney as a pathway for the excretion of any vitamin C that might not be required by the organism. Numerous data have been obtained bearing on the variations in urinary vitamin C in health and disease. Correlation of these urinary analyses with clinical manifestations of scurvy has established the value of a study of the excretion of the vitamin as an aid in the detection of a deficiency. Thus it has been established<sup>1</sup> that in normal persons the urinary excretion of cevitamic acid reaches levels that are proportional to the intake of the vitamin. Surprisingly little variation was found between individual normal subjects, the same daily dose of vitamin given to a number of persons producing after a time an almost identical rate of excretion. Furthermore, the percentage excretion of a dose of 600 mg. of vitamin C given to healthy persons apparently depended on the previous level of excretion of the vitamin. For example, when the habitual excretion was 33 mg. for a twenty-four hour period, 27 per cent of the 600 mg. dose was recovered in the urine; if the normal twenty-four hour excretion was 14 mg., only 6 per cent of the same dose was excreted. In view of these results it may be said that the diet has provided insufficient vitamin C when the daily excretion falls below 10 to 15 mg. a day or when a standard test dose of 700 mg. fails to give a response on the second day. In other words, a person with a low daily excretion of vitamin C will generally retain the major portion of a single large administered dose of this factor. Under these conditions, therefore, there appears to be a replenishment of the depleted tissue stores.

This question of vitamin storage and vitamin reserves is of considerable importance in medicine. The magnitude of these reserves and the length of time required for their depletion are factors that are significant in determining the rapidity with which vitamin deficiencies manifest themselves and the rate of recovery from the deficiency when adequate amounts of the proper vitamin are administered. In times of restricted nutrition imposed by either personal or national economic stress, inhabitants of a given area may be ingesting certain of

the vitamins in quantities that are subminimal with respect to the daily requirement. Resistance to the effects of dietary deprivation then becomes solely dependent on the stores of these dietary accessories in the body tissues. The extent of this storage and the amount of vitamin required to saturate the tissues thus become problems of fundamental importance.

Studies on the storage of vitamin C by normal adults have recently been reported by O'Hara and Hauck.<sup>2</sup> These investigators have looked into the urinary excretion of vitamin C in persons in a known state of saturation with respect to this vitamin. The studies were conducted on four normal adult women and were arranged to make possible the determination of the vitamin C intake necessary to reestablish saturation of the tissues after prolonged administration of a diet poor in this factor. The basal diet was adequate with respect to all other nutritive factors but contained only 5 mg. of vitamin C. This diet was ingested for approximately thirty days, following which it was supplemented daily with 200 mg. of cevitamic acid in the form of orange juice. The latter regimen was continued until the subjects were saturated, as evidenced by failure to show further increases in urinary output of vitamin C on a constant high intake. In addition to the quantitative analyses, capillary resistance studies were conducted. The latter, however, yielded variable results and could not be correlated with the urinary excretion of vitamin C. During the period on the basal diet the daily urinary output of the vitamin fell sharply, reaching a low level of 15 mg. within one to two days. All subjects showed a general tendency to decreasing excretion of vitamin C as the period on the basal diet alone was continued. The experiments were not intended to be continued until clinical signs of scurvy appeared, but the urinary analyses which showed a depletion of the body stores of vitamin C were supported by suggestive symptoms of scurvy, which appeared in one of the subjects. In the latter case the gums on the left side of the mouth on both upper and lower jaws from the first premolars through the second molars were swollen, edematous and purple. Since this occurred during the fourth week on the basal diet and disappeared promptly after orange juice was administered, it may probably be interpreted as a symptom of deficiency of vitamin C. With this exception, however, clinical symptoms suggestive of scurvy were not found in the subjects.

When orange juice was given following a period of deprivation, the vitamin C ingestion amounted to from 1,000 to 1,600 mg. before a noticeable increase in excretion occurred. Saturation occurred when from 2,200 to 2,800 mg. of the vitamin had been taken. Approximately four fifths of this quantity was not accounted for in the urine and it seems probable, therefore, that a large part of this quantity was stored. An estimation

1. Abbasy, M. A.; Harris, L. J.; Ray, S. N., and Marrack, J. R.: *Lancet* 2: 1399 (Dec. 21) 1935.

2. O'Hara, P. H., and Hauck, H. M.: *J. Nutrition* 12: 413 (Oct.) 1936.

Irwin Schulz and Lemuel D. Smith, all of Milwaukee; Henry L. Greene and Herman W. Wirka, Madison, and Ralph M. Carter, Green Bay. In pediatrics the speakers were Drs. John E. Gonce Jr. and Horace K. Tenney Jr., Madison; Mynie G. Peterman, Milwaukee, and Henry A. Sincoc, Superior. Instructors in cardiology were Drs. Chester M. Kurtz and Harold E. Marsh, Madison, and James A. Evans, La Crosse. In addition to the scientific program a discussion of legislative problems was presented at each meeting by the president, the secretary or the assistant secretary of the state society.

### GENERAL

**Fund for Advancement of Laryngology and Rhinology.**—The secretary of the American Laryngological Association, Dr. James A. Babbitt, Philadelphia, announces that the sum of \$500 has accrued from the Casselberry Fund and is now available in part or as a whole for a prize award, decoration or the expense for original investigation or research in laryngology and rhinology. Theses or reports of work must be in the hands of Dr. Babbitt, 1912 Spruce Street, Philadelphia, before February 1 of any given year.

**Dr. Boudreau Appointed Director of Milbank Fund.**—Dr. Frank G. Boudreau, chief of the service of epidemiologic intelligence and public health statistics of the League of Nations, Geneva, Switzerland, has been appointed executive director of the Milbank Memorial Fund, New York, to succeed the late Edgar Sydenstricker. Dr. Boudreau, a native of New Glasgow, Que., was born in 1886 and graduated from McGill University Faculty of Medicine, Montreal, in 1910. In 1911, he was appointed epidemiologist to the state board of health of Ohio, remaining in that position until 1925. During the World War he saw service in the United States Army in France, Belgium and England. Appointed statistician-epidemiologist with the Health Organization of the League of Nations in 1925, Dr. Boudreau has been made chief of that service and is also in charge of the League's system of liaison with health administrations. For a time in 1933 he was acting director of the health organization of the League during the absence of Dr. Ludwig Rajckman on an extended stay in China.

**Meeting of Bacteriologists—Dr. Novy Honored.**—James M. Sherman, Ph.D., professor of bacteriology, Cornell University Medical School, New York, was chosen president of the Society of American Bacteriologists at its annual meeting in Indianapolis, December 30. Other officers are Paul F. Clark, Ph.D., Madison, Wis., vice president, and Ira L. Baldwin, Ph.D., Madison, Wis., secretary-treasurer. Honorary membership was conferred on Dr. Frederick G. Novy, professor emeritus of bacteriology at the University of Michigan Medical School, Ann Arbor. Dr. Novy is a charter member of the society and served as its president in 1904. The speakers on the program included the following:

Dr. Alice C. Evans, National Institute of Health, Washington, D. C., Human Infections with *Brucella Melitensis* Variety *Melitensis*.  
Claude E. Zohell, Ph.D., and Karl F. Meyer, Ph.D., University of California Medical School, San Francisco, Growth Zones of the *Brucella* in Semisolid Media.

Miss Marjorie B. Patterson, B.S., and Dr. Robert L. Preston, New York Post-Graduate Medical School and Hospital, New York, Experimental *Staphylococcus Arthritis* in Rabbits: Bacteriologic and Pathologic Observations.

C. T. Butterfield, principal bacteriologist, U. S. Public Health Service, stream pollution investigations, Cincinnati, The Purification of Sewage by Bacteria in Pure Culture.

Louis A. Julianelle, Ph.D., associate professor of applied bacteriology and immunology, Washington University School of Medicine, St. Louis, The Immunologic Specificity of *Staphylococci*.

**International Congress of Radiology in Chicago.**—Plans are under way for the Fifth International Congress of Radiology to be held at the Palmer House, Chicago, September 13-17. Contributions for the program are now being received and those who wish to participate are asked to apply to the president of the Congress, Dr. Arthur C. Christie, 1835 Eye Street N.W., Washington, D. C., stating the subject they wish to present. Participants in the program must be members of the congress; application for membership should be made to the secretary of the congress, 2561 North Clark Street, Chicago. If possible, the application for a place on the program should be accompanied by a 500 word abstract. In any case such abstract must be received by the president not later than April 1 and the full text of the paper by May 1. Abstracts are to be published in three official languages, English, French and German, at least six weeks prior to the congress. The full texts will also be translated and will be projected on the screen in the other languages while they are being delivered. Prompt transmission of the abstract and text will greatly facilitate the translation, publication and preparation of films for projection.

**Medical Bills in Congress.**—*Bills Introduced:* S. 421, introduced by Senator George, Georgia, proposes to reduce the rate of retirement pay to emergency officers that was in effect prior to March 19, 1933. S. 629, introduced by Senator Thomas, Utah, proposes to create an executive department of the government to be known as the Department of Education and Public Welfare. H. R. 48, introduced by Representative Ramsay, West Virginia, and H. R. 1627, introduced by Representative Dirksen, Illinois, propose to make it unlawful to sell certain spirits containing alcohol produced from materials other than cereal grains. H. R. 2274, introduced by Representative Pierce, Oregon, proposes to provide pensions for persons who served ninety days in foreign service under the jurisdiction of the Quartermaster General, Surgeon General of the United States Army, the Secretary of the Navy or Marine Corps, during the Spanish-American War, including the Philippine Insurrection and the Chinese Boxer Rebellion. H. R. 2280, introduced by Representative Ferguson, Oklahoma, in proposing appropriations for emergency relief in stricken agricultural areas, provides for the supplying of hospitalization and medical care to persons in need. H. R. 2308, introduced by Representative Cannon, Missouri, proposes to reenact all public laws granting medical and hospital treatment, domiciliary care, compensation and other benefits to veterans of the World War that were repealed by the Economy Act of March 20, 1933. H. R. 2551, introduced by Representative Whelchel, Georgia, proposes to reenact all laws in effect on March 19, 1933, granting pensions to veterans. H. R. 2751, introduced by Representative Connery, Massachusetts, proposes to recognize the public service rendered by soldiers who volunteered and served in trench fever experiments in the American Expeditionary Forces. H. R. 3009, introduced by Representative Fulmer, South Carolina, proposes to provide for federal cooperation with the several states in the care, treatment, education, vocational guidance and placement, and physical rehabilitation of persons under the age of 21 years "who have some physical defect such as affections of the joints, affections of the bones, disturbances of the neuromuscular mechanism, congenital deformities, static and other acquired deformities that may be corrected or improved by orthopedic surgery or other surgical and medical care." H. R. 3035, introduced by Representative Scruggs, Nevada, proposes to authorize the President to employ unemployed citizens of the United States in the discovery and development of the mineral resources and to provide them with such medical attendance and hospitalization as may be necessary. H. R. 3130, introduced (by request) by Representative Bacon, New York, proposes to extend the status of veterans of the World War to persons enlisted and serving on United States Shipping Board vessels during the World War in war zones. H. R. 3298, introduced by Representative Buchanan, Texas, proposes to include Roger P. Ames among those honored by the act recognizing the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever. H. R. 3300, introduced by Representative Dunn, Pennsylvania, proposes to establish a nation-wide system of social insurance by the enactment of a Workers' Social Insurance Act. H. R. 3412, introduced by Representative Ludlow, Indiana, proposes to erect a 200 bed addition to the existing Veterans' Administration Facility at Indianapolis, for the treatment of general medical and surgical disabilities. H. R. 3419, introduced by Representative Pfeifer, New York, proposes to prevent the pollution of navigable waters of the United States. H. R. 3469, introduced by Representative Fernandez, Louisiana, proposes to erect a 300 bed veterans hospital in the parish of Orleans, Louisiana. H. R. 3491, introduced by Representative Collins, Mississippi, proposes to provide for adequate dental service for individuals of the Military Establishment of the United States.

### CORRECTION

**Professor Dessauer a Catholic.**—We are informed by Dr. Leopold Jaches of New York that the statement in the Vienna letter (*THE JOURNAL*, January 2, p. 57) that Professor Dessauer is a Jewish refugee from Germany now residing in Istanbul is incorrect. He states that Professor Dessauer is not a Jew but a devout Catholic and that the name of Dessauer first appeared in the records of the city of Aschaffenburg in the vicinity of Frankfurt) in 1805 and has since remained in the records of the Catholic church. The great grandfather of Professor Dessauer was buried in the Catholic Cemetery of Aschaffenburg. Professor Dessauer is a refugee from Germany and is at present ordinarius for radiology and physics at the University of Istanbul.

inspected by an approved health authority at intervals of six months with reference to the potability of the water. Furthermore, water for filling the tanks should be drawn only from certified sources. The code also imposes regulations concerned with parking, food supply, ventilation, cleanliness and screening. The use of pasteurized milk exclusively is recommended, and trailer travelers are warned concerning the need for securing medical attention if illness arises. The desirability of vaccination of children against smallpox and their inoculation against diphtheria is stressed. Even if no further increase in the number of individuals traveling and living in automobile trailers should occur, it is definitely incumbent on local health authorities to enact and enforce suitable legislation covering the health problems raised by this migratory population.

### HOSPITAL INSURANCE PLANS

Out of 172 group hospitalization and hospital insurance plans recently addressed by the Bureau of Medical Economics of the American Medical Association, ninety were found active and eighty-two inactive. Of the active plans, fifty-six were found to be operating and thirty-four in the state of established proposals. Fourteen new plans have recently been proposed. Thus the present status may be defined as one of active experimentation in an effort to find out the workable features and thus maintain systems capable of meeting existing needs. Various investigations indicate that somewhere between 500,000 and 700,000 persons are now members of such plans. Incidentally, three plans have 50 per cent of the entire membership, and ten plans have 80 per cent of the entire membership. In Chicago, the plan proposed through the Hospital Council involved the setting up of a hospital service corporation as a nonprofit corporation, organized under the Illinois act exempting a nonprofit service corporation from the insurance code of the state. This plan has been under active consideration by a committee of the Chicago Medical Society, which proposed six requirements before it could place the approval of the Chicago Medical Society on the plan. Of these, the chief demand is that all matters of medical administration and medical policy be referred to the Chicago Medical Society, whose decision in these instances shall be final and binding both on the Chicago Hospital Council and on its member hospitals. Unfortunately, the Council of the Chicago Medical Society has not yet accepted the report of its committee, owing to the apparent insistence of one of its members that the medical society do not enter into the arrangement unless it has a guaranty of 51 per cent of the directorate, an insistence to which the Hospital Service Corporation may hesitate to consent. It is interesting to realize that Chicago has already had ten group hospitalization plans besides the Hospital Service Corporation, not one of which has attained even slightly significant proportions. Two of these plans were organized under the same law that created the Hospital Service Corporation and both secured articles of incorporation notwithstanding the fact that they were promoted by hospitals considered to be unable to give first class service. Another unfortunate aspect of the situation is the fact that the propaganda and

promotion associated with the Hospital Service Corporation have brought into the field various unethical imitators, one of them advancing himself by the circularization of the public in his vicinity with a schedule labeled the Chicago Hospital Service Plan, a vague imitation of the proposition advanced by the Hospital Service Corporation. It will apparently become the obligation of those who actively promote such plans under legitimate auspices to protect the public at the same time against illegitimate promoters, through exercising the rights of any business group to the protection of their names and style in the courts.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARKANSAS

**Bill Introduced.**—S. 11, to amend the osteopathic practice act, proposes (1) to authorize a licensed osteopath "to practice osteopathy in all its branches as taught and practiced in legally incorporated schools of osteopathy," (2) to define "legally incorporated schools of osteopathy" as "those recognized as reputable and approved by the American Osteopathic Association," and (3) that all licensed osteopaths "shall be qualified to sign birth and death certificates and all other certificates pertaining to the public health."

### CALIFORNIA

**Meeting on Heart Disease.**—The Los Angeles Heart Association held a two day session at the Los Angeles County Medical Association building, January 28-29. The first evening there was a joint meeting with the Los Angeles Clinical and Pathological Society. Round table discussions were led by Drs. Howard F. West, Burrell O. Raulston, Verne R. Mason, John W. Budd Jr. and William H. Leake. Other speakers included:

Dr. James F. Churchill, San Diego, Diagnosis of Cardiac Infarction.  
Dr. Hilmar O. Koefod, Santa Barbara, Diuretics.  
Dr. William Dock, San Francisco, The Value of Auscultatory Findings in Heart Disease.

Friday evening a joint meeting of the society with the Los Angeles County Medical Association was addressed by Drs. Dock and Arthur M. Hoffman on "Significance of Dyspnea" and "Heart Disease as a Community Problem" respectively.

**Bills Introduced.**—S. 59 and S. 62 to amend the state narcotic drug act, propose (1) to prohibit a person, in connection with the prescribing, furnishing, administering or dispensing of any narcotic drug, to give a false name or address or make any false statement to any person authorized by law to prescribe, furnish, administer or dispense any such drug; (2) to eliminate from the substances exempted from the law preparations containing not more than "one-fourth grain of morphine" or "one-sixteenth grain of heroin"; (3) to forbid the furnishing of any narcotic drug pursuant to a telephone order of a physician and surgeon except that in an emergency a pharmacist may deliver any narcotic drug through an agent pursuant to a telephone order if the agent is supplied with a properly prepared prescription before delivery is made; (4) to define a narcotic addict as "any person who takes or otherwise uses any of the narcotics enumerated in section 1 of this act, and who is so far addicted to the use of such narcotics as to have lost the power of self control with reference to his addiction, except that when such user of narcotics is suffering from an incurable disease or an accident or injury or from the infirmities of age and such narcotics are furnished, prescribed or administered to him in good faith and in the course of his professional practice by a physician and surgeon duly licensed in this state, in the course of treatment for such disease, ailment, injury or infirmities, and are not so furnished or prescribed in order to satisfy the narcotic addiction of a user of narcotics, such person shall not be held to be an addict within

the same conclusion, that radioactive substances should never be introduced and left in the human body because of the danger of inducing malignant tumors.

#### CANCER AND THE SEX HORMONES

The recent studies of Cramer and Horning on the carcinogenic properties of the sex hormones were reviewed by Dr. Gye, who said that they demonstrate clearly the importance of susceptibility in the genesis of cancer. "The specificity of the results suggests the question whether there may not be a range of susceptibilities which, under the changing environment of the modern world, are liable to be brought under observation." The discovery that these sex hormones were carcinogenic had engendered some nervousness among the medical profession, since they were widely used in the treatment of gynecologic disorders, but there was no reason to fear that their skilled administration might produce cancer.

#### Therapy of Cancer by High Voltage Radiation

Great attention continues to be devoted in this country to the radiotherapy of cancer. The latest advance is the Mozelle Sasoon High Voltage X-Ray Therapy Department at St. Bartholomew's Hospital. It was opened by Mrs. Meyer Sasoon, who has financed this addition to the hospital's equipment for treating cancer. The department has been designed to overcome the three main limitations to radiotherapy. In addition to the difficulty of delivering an adequate dose of radiation to a tumor deep in the body without damage to outlying structures, it has not been possible to give doses within a reasonably short exposure time, while there existed a narrow margin of safety because of the small difference in radiosensitivity between normal and malignant tissues. The new installation, which may be operated at from 250,000 to 1,000,000 volts, is expected to remove these difficulties by reason of the fact that x-rays of a greater penetrative power, of a higher intensity and of shorter mean wavelength can be used.

Some novel features have been introduced into the new department. Radiation-proof walls, constructed of interlocking barium concrete, separate the treatment and generator rooms from the administrative section. The doors of the treatment section of the building are constructed of heavy steel plates and are designed to prevent radiation leakage. Electrical interlocks on the doors of the x-ray tube render the apparatus absolutely safe.

The x-ray tube is a massive construction 30 feet long. From a small aperture the x-ray beam is directed on the patient through an applicator. Since the tube is permanently fixed to the walls, although the applicator cylinder can be rotated independently, the floor of the treatment room has been made movable, so that the horizontal position of the patient in relation to the tube may be adjusted as desired. Communication between the control room and the patient receiving treatment is possible by a two-way microphone and loud speaker, and the patient can be kept under observation by a novel periscopic system of eight concave mirrors. At the opening ceremony the physicist Lord Rutherford congratulated the hospital on its valuable acquisition and said that the new department should put this country in the lead in the experiments of the treatment of cancer by high voltage radiation.

#### Clinic for Diabetic Children

The first clinic in this country for the treatment of diabetic children has been established at King's College Hospital, London. There are diabetic clinics at the other great teaching hospitals, but none especially devoted to children. Presiding at the opening, Dr. G. F. Still (pediatrician) said that twenty-five years ago the idea of a diabetic clinic for children would have seemed a grim jest. Diabetes was uncommon in children and the outlook in those days for a child was so black that

there could have been but a meager attendance at any clinic. Some thought that the disease was becoming more frequent in childhood. If so there was to be set against this the fact that the outlook had entirely altered. With discovery of insulin, it had become bright and hopeful. Nowadays, with intelligent care in dieting, which was an essential adjunct to the use of insulin, a diabetic patient might look forward to a happy and useful life. King's College had the good fortune to be able to put in charge of the new clinic Dr. R. D. Lawrence, whose skill and experience in the treatment of diabetes was mature.

#### The British Pharmacopoeia

In accordance with the principle of decennial revision, the next edition of the British Pharmacopoeia would be published in 1942; but the Pharmacopoeia Commission of the General Medical Council, recognizing the desirability of regular alternation at five yearly intervals with the United States Pharmacopoeia, has suggested that, as the eleventh of the United States series was published in 1936, efforts should be made to publish the next edition of the British Pharmacopoeia in 1941. The commission has invited clinicians, pharmacologists, pharmacists and other experts to assist in the revision. The response received has been generous. The cooperation of committees in India and the dominions has also been invited.

#### One Hundred and Fifty Thousand Dollars a Year for an Institute of Chemotherapy

At the seventy-fourth anniversary dinner of the Royal Society, Mr. Neville Chamberlain, chancellor of the exchequer, said that he had consented to give a grant of \$150,000 a year toward the establishment of an institute of chemotherapy. That allocation was in response to a request from the Medical Research Council, backed up by the Department of Scientific and Industrial Research.

#### PARIS

(From Our Regular Correspondent)

Dec. 26, 1935.

#### The French Urologic Congress

This year's meeting of the French Urologic Congress was held in Paris during the week of October 5. The president for 1936 was Dr. Octave Pasteau. In recognition of his services as secretary during the last thirty years, Dr. Pasteau was presented with a medal following addresses by Professors Legueu, Verhoogen and Nogues. The officers for the 1937 congress are Dr. Lepoutre of Lille, president, and Dr. Levenant of Paris, vice president. The subjects chosen for the 1937 meeting and those appointed to report on them are surgical treatment of medical nephropathies, Drs. Chabanier, Gaume and Lobo-Onell, and indications and results of endoscopic resection of the prostate, Professor Gayet and Dr. Imbert. Among the foreign corresponding members present were Drs. Keyes and Gutierrez of New York and Dr. C. H. de T. Shivers of Atlantic City, N. J. The subject chosen for this year's discussion was surgical aspects of anomalies of the kidney and ureter. The reporter was Dr. Darget of Bordeaux. As to abnormal vessels which obstruct the ureter, he said that their division, even when the vessel is a relatively important one, has not been followed by any complication. This is not the view of the majority of American urologists. Plastic operations of the Fenger or Kelly type for obstruction (congenital) at the ureteropelvic junction are seldom employed at present. Resection of the renal pelvis is often an adjuvant procedure in certain cases of hydronephrosis. Lateral anastomosis of the ureter and renal pelvis, preferably as low as possible, is the operation of choice in obstruction at the ureteropelvic junction. In spite of the disappearance of symptoms following the various plastic procedures, a certain degree of pyelectasis persists and hence such operations should be done before too much dilatation of the

Clinical Standpoint"; Earle E. Smith, Bardwell, "Treatment of Pleurisy" and Willis R. Moss, Clinton, "A Case of Mastoiditis and Anemia."—Dr. John A. Kolmer, Philadelphia, addressed the Jefferson County Medical Society, Louisville, January 4, on "Immunity and Vaccination in Infantile Paralysis."

**State Commissioner of Health.**—Dr. Arthur T. McCormack, secretary of the state board of health, Louisville, will now bear the title state commissioner of health, in accordance with a statute passed by the 1936 legislature authorizing reorganization of the department. Dr. McCormack has served as state health officer since 1912. He is also secretary of the Kentucky State Medical Association and editor of the *Kentucky Medical Journal*. At the 1936 meeting of the American Public Health Association he was made president-elect of the association.

## LOUISIANA

**Dr. Nix Appointed Director of Graduate School.**—Dr. James T. Nix, New Orleans, has been appointed director of the Graduate School of Medicine of Louisiana State University. Although plans were formulated for the development of the graduate school in the spring of 1931, inadequate facilities and stress on the growth of the undergraduate school kept the advanced department inactive until the appointment of Dr. Nix, Nov. 26, 1936. Actual work started December 9. Short courses will be offered in 1937.

**Meeting in Memory of Dr. Lewis.**—The New Orleans Gynecological and Obstetrical Society and the Orleans Parish Medical Society held a joint meeting, January 18, to honor the memory of the late Dr. Ernest Sydney Lewis. The speakers were Drs. John F. Dicks, New Orleans, who presented "Memoirs of Dr. S. M. D. Clark," and Robert A. Wilson, Brooklyn, "The Initiation of Respiration in Asphyxia Neonatorum." Dr. Lewis was chairman of the Section on Obstetrics and Diseases of Women and Children of the American Medical Association from 1878 to 1880; professor of materia medica, therapeutics and clinical medicine, 1873-1876; professor of obstetrics and diseases of women, 1876-1911, and from 1911 to his death in 1935 professor of obstetrics and gynecology, emeritus, Tulane University of Louisiana School of Medicine. In 1867 he served as state health officer. He died Aug. 12, 1935.

## MASSACHUSETTS

**Pediatric Meeting.**—The New England Pediatric Society met at the Children's Hospital Amphitheatre, Boston, January 15. The speakers were Drs. Warren E. Wheeler on "The Use of Ammonium Mandelate in Urinary Infections," and Benjamin W. Carey Jr., "Prontosil: Impressions on Its Use in Streptococcus Infections." Both are of Boston. Orthopedic and surgical patients were presented, and in the evening Dr. Henry F. Helmholz, Rochester, Minn., presented a paper at the Boston Medical Library entitled "Thyroid Disorders in Children."

**Personal.**—Honorary fellowship in the Royal College of Physicians and Surgeons of Canada was recently conferred on Dr. Henry A. Christian, Hersey professor of the theory and practice of physic, Harvard University Medical School, Boston. —Dr. Harold F. Norton, Hyde Park, senior physician at the Boston State Hospital, has been appointed superintendent of the institution, succeeding Dr. James V. May, retired. According to the *Boston Traveler*, this is the first time in the history of the hospital, which is 100 years old, that a Massachusetts physician has been named superintendent.

**Dr. Holmes Honored.**—Dr. George W. Holmes, clinical professor of roentgenology, Harvard University Medical School, Boston, was guest of honor at a dinner, December 28, celebrating his sixtieth birthday and the twenty-fifth anniversary of his appointment as roentgenologist of the Massachusetts General Hospital. At a dinner, given by his students and assistants, Dr. Holmes was presented with a special copy of the *American Journal of Roentgenology* for December, which is designated the George W. Holmes Anniversary Number. It is made up of contributions by his former students all over the country, according to the *New England Journal of Medicine*.

**Bills Introduced.**—S. 182 proposes to establish a board of registration of chiropractors and to regulate the practice of chiropractic, defined as "the science of locating, and removing, by hand only, interference with the transmission or expression of nerve force in the human body, where such interference is indicated or misalignment or subluxations of the vertebral column appear. It excludes operative surgery, prescription or

use of drugs or medicine, or the practice of obstetrics, except that the x-ray may be used solely for the purposes of examination." Applicants for such licenses must be 21 years of age, of good moral character, be high school graduates, be graduates from reputable chiropractic schools which require courses of resident instruction of four academic years of not less than thirty-two weeks each and pass written examination to be given by the board. However, persons who have been practicing chiropractic in Massachusetts, whether in violation of law or not, for one year prior to the enactment of the bill may receive a license to practice without examination. S. 183 proposes to establish a board of registration in osteopathy and to regulate the practice of osteopathy. No definition of osteopathy is given in the bill and presumably such practitioners would be authorized to practice without restriction. An applicant for such a license is to be required to possess a high school education or its equivalent, to have completed two years of premedical collegiate work, including physics, chemistry and biology, in a college or university approved by the board, and to have attended courses of instruction for four years of not less than thirty-two school weeks in each year in a legally chartered school of osteopathy. S. 184 proposes to require hospitals receiving public support to permit licensed osteopaths to practice within their confines on the same terms as licensed physicians and surgeons are permitted to practice therein. H. 413 proposes to require the appropriate school committee to cause every child in the public schools to be examined at least once a year to ascertain defects in sight or hearing and other physical defects. The tests of sight and hearing are to be made by teachers, directions for which are to be prescribed by the department of public health. The physical examination is to include especially the examination of the feet by a person qualified to examine the feet. H. 759 proposes to require (1) the consent of a patient before a physician may remove any organ, (2) the physician to submit to the patient a written explanation of the necessity of its removal and (3) the preservation of any organ so removed until the patient has directed its disposal. H. 383 proposes a statewide system of compulsory health insurance applicable to all workers except (1) those making in excess of \$1,800 a year; (2) agricultural workers; (3) adherents of any established church or cult "whereby such adherence or membership prejudices the employee by the teachings inculcated," and (4) a member of an industrial medical service plan. The benefits proposed to be conferred on workers by the proposed insurance scheme include the services of a physician when required for preventive, diagnostic or therapeutic treatment and care, including antepartum and maternity treatment and surgical and specialist services and necessary hospital maintenance and care in a public ward, including drugs, medicines and dressings. These benefits it is proposed to provide by means of contributions to be exacted from both worker and employer.

## MICHIGAN

**Bill Introduced.**—H. 54, to amend the workmen's compensation act, proposes to require an employer to furnish and pay for medical, surgical and hospital services and medicines to an injured employee so long as they are needed. The present law imposes this liability on an employer only during the first ninety days after an industrial injury.

## MINNESOTA

**Classes for Crippled Children.**—Social security funds will be used to finance classes for crippled children who are unable to attend regular schools, according to *Minnesota Medicine*. Dr. Herman E. Hilleboe, St. Paul, of the state board of control is in charge of the program.

**Bills Introduced.**—S. 88 proposes to permit a feebleminded person under the guardianship of the state board of control to contract marriage on the approval of the board of control provided the feebleminded person is sterile. H. 71, to amend the workmen's compensation act, proposes to make compensable all occupational diseases or infections arising "naturally" out of an employment.

**Courses for Practicing Physicians.**—The Center for Continuation Study of the University of Minnesota in cooperation with the medical school and the state medical association began a series of graduate courses for practicing physicians January 17 to continue through February 13. The first week was devoted to traumatic surgery; the second to obstetrics and gynecology; the third will be given over to pediatrics, and the fourth to internal medicine. The courses consist of lectures, clinics, demonstrations, ward walks, seminars and practical work, and each student will be permitted to present his own problems to

Hospital, in preventing contamination in children admitted for noncontagious ailments. The special intern also is obliged to notify the family physician, the medical school inspector and the parents of the possible future appearance of certain contagious diseases which have been attenuated by the prophylactic serum injections. Thus a contagious disease that might appear in one of these vaccinated children will be rapidly detected and early isolation thereby made possible. Debré made a plea for the appointment of a commission to study the creation of a special service in all children's hospitals to prevent contagion arising after admission to noncontagious disease wards.

#### Etiology of Volkmann Contracture Following Fractures Around Elbow

At the October 21 meeting of the Académie de chirurgie a case of Volkmann's contracture following a supracondyloid fracture of the humerus was reported by Folliasson of Grenoble. The discussion of this case by Etienne Sorrel, who has had a large experience in children's surgery, was of particular interest. The child was 8 years of age and had sustained a supracondyloid fracture of the humerus with marked displacement of fragments two months before being seen by Folliasson. The latter found a typical Volkmann syndrome. There was evidence of complete sensory and motor paralysis of the median nerve. Although at operation the brachial artery was found to be normal, a periarterial sympathectomy was done. The median nerve was embedded in a mass of scar tissue, which was removed. In order to overcome the deformity of the wrist and fingers, the second row of carpal bones except the trapezius was resected and the flexors of the fingers were separated at their point of origin from the bone. There was slight improvement following these procedures in spite of prolonged physical therapy. Folliasson raised the question whether a resection of the bones of the forearm and of the compressed portion of the median nerve followed by a nerve graft were not indicated. The orthopedic surgeon Etienne Sorrel, in commenting on this case, said that the brachial artery had remained intact, confirming recent observations that the frequency of injury of this vessel as a complication of elbow fractures has been greatly exaggerated. It cannot be denied that in a certain number of reported cases (Leriche, Lance, Carcassone, Mathieu) injury of the artery and vasomotor nerves existed, but this is exceptional, as is further proved by the absence of improvement following sympathectomy or arteriectomy. In Folliasson's case neither the artery nor the vasomotor nerves were affected, the damage being limited to the median nerve. The more frequently operations for relief of Volkmann's contracture are performed, the more commonly does one find a nerve injury noted. Such observations have been confirmed by numerous examinations by competent neurologists before any operation; hence it follows that the vascular and vasomotor factor plays less and less of a part than was formerly taught. Sorrel in a large children's fracture service has observed only four cases of Volkmann's contracture and this is the experience of many other surgeons. The etiology of the syndrome still remains to be cleared up. Neither the sympathectomy nor the lengthening of the flexors was of any benefit in Folliasson's case, because as to the latter step Sorrel believed there was already too much retraction of the flexors present when the patient was first seen. As to the proposed resection of both bones of the forearm, the success of such an intervention depends on the extent of damage to the median nerve. If signs of the latter exist within the first few days after a supracondyloid fracture of the humerus, immediate operation is indicated to avoid a potential Volkmann contracture. The symptoms are marked edema, cyanosis and coldness of the forearm and hand, associated with anesthesia and paralysis of the fingers. Even if there is no such evidence of nerve injury but only marked displacement of fragments, an open reduction will forestall future complications, according to Sorrel.

#### BERLIN

(From Our Regular Correspondent)

Dec. 14, 1934

#### Persons Engaged in Care of Sick

The National Health Bureau has issued an official statistical report on the number of persons actively engaged in the medical, nursing and kindred professions as of Jan. 1, 1935. The report includes statistics on all other groups the members of which derive their livelihood from the care of the sick. In all, 286,949 persons were included within the survey. That a majority were females is due to the fact that by far the largest unit listed comprises members of the nursing profession. The medical profession, as the keystone of all the professional groups covered by the survey, represented 17 per cent of the foregoing grand total; its members numbered 47,419 persons who are licensed to practice medicine in Germany. There were 44,491 men physicians and 2,928 women physicians. These figures represent an increase in the total number of physicians of 0.3 per cent (144) over 1934. There were 12,088 licensed dental physicians, of whom 785 were women; 10,981 registered pharmacists, including 549 women; 25,737 midwives; 20,298 dentists (dental practitioners without university training), including 2,353 women; 11,922 bone setters, masseurs and so on, including 5,494 women; 126,008 trained nurses, of whom the vast majority (104,822) were women; 6,869 nurses especially trained to care for infants; 1,240 confinement assistants; 5,581 disinfectors, including 593 women, and finally there were 14,023 heilpraktiker (lay practitioners who by no means are to be considered as physicians but rather as so many quacks), including 3,359 women. Lumping all these groups together as a unit, the distribution according to sex was found to have been 130,520 men and 156,428 women. While the foregoing figures may be regarded as official, they still lack uniformity, as this type of statistical survey is relatively new and not all of the German states have instituted compulsory registration for the members of all these groups.

Only a slight increase took place in the number of regular physicians during 1934. There were 7.2 physicians to each

TABLE 1.—Distribution of Specialists as of Jan. 1, 1935

Totals.....	14,711	14,991	101	31.4	771	5.2

10,000 of population and 10.1 physicians in each 100 square kilometers of area, or one doctor to each 1,388 inhabitants and to each 9.9 square kilometers of area. The previously mentioned 144 physicians were chiefly women, 127 new women physicians to only seventeen men. From this one may conclude that the proportion of women physicians will undergo a yet greater increase in the near future, since it is significantly higher among the rising generation as compared to the older generation of physicians. In the year 1933-1934, 15.4 per cent

**Society News.**—At a meeting of the Southern Oklahoma Medical Association in Ardmore, December 7, the speakers included Drs. Robert B. Giles, Dallas, Texas, on "Classification and Medical Treatment of Peripheral Vascular Diseases"; Hervey A. Foerster, Oklahoma City, "Rational Treatment of Syphilis," and Mr. O. E. Shaw, superintendent of Ardmore schools, "Relation of Physicians and Teachers for the Benefit of Public Health."

### PENNSYLVANIA

**Hospital News.**—A \$10,000 fireproof building was opened December 8 at the country branch near Malvern of Rush Hospital for Consumption and Allied Diseases, Philadelphia. The new building replaces one destroyed by fire in January 1936, in which two children were burned to death.

**Society News.**—Dr. Maxwell Lick, Erie, president of the Medical Society of the State of Pennsylvania, addressed the Lycoming County Medical Society, Williamsport, January 8, on "Diagnosis of Acute Abdominal Tragedies."—A North-eastern Pennsylvania chapter of the National Society for the Advancement of Gastro-Enterology will be organized at a meeting in Easton, February 3. Dr. Norman W. Elton, Reading, will give an address on "The Role of Duodenobiliary Drainage Ulcer and Biliary Tract Disease."—Dr. William L. Estes Jr., Bethlehem, addressed the Lehigh County Medical Society in December on early diagnosis of cancer.

**Bills Introduced.**—S. 26 proposes to authorize the hospitalization of tuberculous patients in state and state-aided hospitals when state owned institutions established for that purpose are unable to provide and care for such patients and to provide that the cost of the care and treatment of such patients shall be paid by the state out of any appropriation made to the department of health and available for the care and treatment of tuberculous patients in state institutions. S. 37 proposes an amendment to the state constitution to prohibit appropriations for charitable, educational or benevolent purposes to any person or community or to any denominational or sectarian institution, corporation or association. H. 99 proposes extensive amendments to the workmen's compensation act. Among other things, the bill proposes (1) to extend to six months, from thirty days, the period following an industrial accident during which the employer must furnish and pay for medical, surgical, dental and nursing services and hospital treatment to an injured workman, (2) to eliminate the provision in the present law which limits the amount of the employer's liability for such services to \$100, and (3) that a worker need not submit to surgical treatment, which in the opinion of at least two qualified physicians might jeopardize his life. H. 126, to amend the workmen's compensation act, proposes to make compensable certain occupational diseases contracted by miners. The bill proposes that the term "occupational disease" shall include only anthracosis, asthma resulting therefrom, or bursitis acquired or resulting from employment in any process involving mining.

### Philadelphia

**Society News.**—Dr. Samuel Barbash, Atlantic City, among others, addressed the Pennsylvania Physical Therapy Association, January 21, on "Medical Diathermy in the Treatment of Diabetic Gangrene."—At a meeting of the Philadelphia Neurological Society, January 22, the speakers included Drs. Ernest A. Spiegel, Philadelphia, and Norman P. Scala, Washington, D. C., on "Cortical Innervation of Ocular Movements," and Drs. Joseph C. Yaskin and Melvin W. Thorne, "The Treatment of Myasthenia Gravis."—Dr. Edwin Beer, New York, delivered the B. A. Thomas Annual Oration of the Philadelphia Urological Society, January 25, on "Some Aspects of Malignant Tumors."—Wendell M. Stanley, Ph.D., Princeton, N. J., addressed the Pathological Society of Philadelphia as guest speaker, January 14, on "Chemical Studies on Crystalline Tobacco Mosaic Virus Proteins."

### Pittsburgh

**Pneumonia Serum Provided by the City.**—Funds to furnish to physicians practicing in private homes and in hospitals specific serum for treatment of pneumonia patients were made available at a special conference between the mayor, the chairman of the city council's committee on health, the city health director and representatives of the medical profession and the pharmacists. Physicians are asked to send sputum promptly to the nearest hospital laboratory; if the analysis indicates pneumonia type I or II, they may send to the health department for the serum indicated. There is no charge for either service.

### RHODE ISLAND

**State Journal Editor Resigns.**—Dr. Frederick N. Brown, Providence, editor of the *Rhode Island Medical Journal* for fifteen years, has resigned. The new editor is Dr. Albert H. Miller, Providence. Dr. Brown is 71 years old. Dr. Miller, who is 63 years old, is a graduate of Columbia University College of Physicians and Surgeons, class of 1898.

### SOUTH CAROLINA

**Bill Introduced.**—H. 9 proposes to repeal the workmen's compensation act approved July 17, 1935, officially cited as Acts of 1936, Act No. 610.

**Society News.**—Speakers at the annual meeting of the Marlboro County Medical Society, Bennettsville, January 8, were Drs. Robert C. Bruce, Greenville, president of the South Carolina Medical Association, on "The Problem of Compulsory Insurance as It Relates to the Practice of Medicine"; Samuel F. Ravenel, Greensboro, N. C., "Nephritis in Children"; James M. Northington, Charlotte, N. C., "Health Care of the Ageing," and Archibald Johnston Buist, Charleston, S. C., "Endometriosis."—The Medical Society of South Carolina, a Charleston organization, has received a bequest of the library of the late Dr. Joseph Hume, formerly of Charleston. The collection contains 250 volumes on urologic subjects and 150 miscellaneous volumes on medicine and medical history. It has been deposited temporarily in the library of the Medical College of South Carolina. Dr. William Atmar Smith is president of the society and Dr. Joseph I. Waring, secretary.

### TENNESSEE

**Bills Introduced.**—S. 91 proposes to authorize the sexual sterilization of certain socially inadequate inmates of state institutions. H. 144 proposes that whenever any man is sentenced to the penitentiary on the charge of rape it shall be the duty of the commissioner of institutions to have him sterilized within thirty days after arrival at prison.

**Mid-South Medical Assembly.**—The fifty-third annual convention of the Mid-South Post Graduate Medical Assembly will be held at the Hotel Peabody, Memphis, February 16-19, under the presidency of Dr. Carl R. Crutchfield, Nashville. Twenty-four guest speakers are listed in the program. Among them are Drs. Esmond R. Long, Philadelphia; Cyrus C. Sturgis, Ann Arbor, Mich.; Sidney D. Kramer, Brooklyn; Andrew C. Ivy, Chicago, Albert Graeme Mitchell, Cincinnati; Russell L. Haden, Cleveland; Jonathan C. Meakins, Montreal, and Harvey B. Stone, Baltimore. Dr. Arthur F. Cooper, Memphis, is secretary.

### TEXAS

**Bill Introduced.**—S. 25 proposes a new pharmacy practice act. Nothing contained in the act is to be construed to prevent (1) the personal administration, compounding or manufacturing of drugs or medicines carried or kept by licensed physicians in order to supply the needs of their patients, (2) the sale, in stores other than pharmacies, of "patent" or proprietary medicines, household remedies or cosmetics when sold in the original unbroken packages only, or (3) the sale of properly labeled insecticides or fungicides and harmless chemicals when used in the arts.

### UTAH

**Bill Introduced.**—S. 23 proposes to require any physician, employed by an industrial employer of labor within the state to make examinations of workers or prospective workers, to file, within five days from the date of making such examination, a written transcript of his findings with the secretary of the industrial commission of the state and to file a copy thereof with the worker or the prospective worker.

### WISCONSIN

**Demonstration Health Unit in Dane County.**—Dr. Erwin F. Hoffman, Cameron, has been appointed director of a health unit established in Dane County as one of three demonstration units in the state made possible by social security funds. Tuberculin testing and goiter prevention will be special objectives of the new department, which will limit its activities to small towns and rural areas outside Madison. Dr. Hoffman graduated from Rush Medical College, Chicago, in 1933.

**Graduate Course on Disabilities in Children.**—During late November and early December meetings were held in thirteen councilor districts of the State Medical Society of Wisconsin to present a course of instruction on "Prevention of Disabilities in Children." Four physicians made up a team of instructors for each meeting. The following were instructors in orthopedics: Drs. David J. Ansfield, Walter P. Blount,

mean expectation of life for infants of both sexes amounts, on the basis of the table of 1932-1934, to 61.1 years compared to a mean expectation of 57.4 years on the basis of the table of 1924-1926.

### The Offspring of the Tuberculous

Little exact statistical information has heretofore been available with regard to the offspring of severely tuberculous male subjects. Interest attaches to investigations carried on in the course of the last three years by Dr. Diehl at a tuberculosis hospital near Berlin. The study was made of patients who presented open, usually far advanced, tuberculosis, as it is pre-

TABLE 3.—Children Begotten in Various Age Groups

Age	Number of Patients	Number of Children Begotten
21-30 .....	361	80

41-50 .....	229	260
51-60 .....	138	250
61 and over .....	34	78

cisely at this stage that a tuberculous person may be regarded as a transmitter of hereditary predisposition to the disease. The uncommonly bad prognosis in active tuberculosis among adults has recently again been described by Braeuning and Neissen: After a follow-up observation period of ten years from the first diagnosis of open tuberculosis, these investigations showed the mortality rate to be 80 per cent. Further observation of the surviving 20 per cent showed a similar further high mortality in the succeeding years. Therefore it is impossible yet to say whether in the long run a final complete cure of open tuberculosis can be spoken of when dealing with larger groups of the openly tuberculous.

Diehl's investigation concerned only 1,115 male patients who presented severe tuberculosis; these he divided into separate age groups and recorded the number of children begotten by the men in each group as in table 3. Thus a total of 908 children could be established as the offspring of these 1,115 tuberculous fathers.

On the other hand, the question of how many children were begotten prior to the father's illness and how many subse-

TABLE 4.—Children Begotten Before and After Manifestation of Tuberculosis

Age of Tuberculous Fathers	Children Begotten Before Manifestation of Tuberculosis	Children Begotten After Manifestation of Tuberculosis
21-30 .....	50	30

41-50 .....	224	36
51-60 .....	234	16
61 and over .....	76	2
	757	151

quently was considered of importance. Onset of the tuberculosis was gaged by the history of pulmonary hemorrhages, fever and presence of tubercle bacilli in the sputum, but not by general complaints of debility and so on. The figures appear in table 4. According to the statistics, the children begotten before the fathers became ill outnumber those begotten subsequently about five to one.

Dr. Diehl assumes that the number of children is somewhat below the average number begotten by healthy fathers at the various corresponding age levels. Still, the number of offspring of these severely tuberculous persons seems formidable enough. Eighty-three children (11 per cent) of those begotten before manifestation of tuberculosis in the father were the offspring of fathers in whose direct ascendancy a tuberculous taint had already existed.

### The New Penal Code

The new penal code, known as the King Charles II Code, provides that those who import narcotic drugs and manufacture them secretly are liable to imprisonment ranging from one to three years and a fine of from 2,000 to 5,000 lei. Those who procure narcotic drugs without a medical prescription or sell them to others, even if gratuitously, are liable to imprisonment of from three to twelve months. Punishment awaits the physician who prescribes a narcotic to an addict. If in consequence of such prescription the health of the person in question is damaged, the punishment is from five to ten years in prison. It is regarded as an offense against public morals and is punishable by from three to twelve months in prison to sell pornographic books, drawings or photos or to import them. Promoting prostitution is liable to imprisonment of from six to twelve months, but if the promoter is the parent or the guardian of the individual, from three to seven years in prison is the punishment. If a girl under age is forced by violence or by means of alcohol or narcotics, the punishment is increased. A man offering protection to a prostitute and accepting money for this is liable to from three to twenty-four months' imprisonment. Procuring involves imprisonment from three to six years.

A new feature of the penal code is the protection of the family. The married mate who carries on an extramarital relation is punished with from one to twelve months in prison, but if the relation is continued also after the starting of the criminal process against him the punishment is doubled. The punishment concerns not only the married mate but also the accomplice. If the couple did not live together when adultery was committed, no complaint can be made.

If youngsters under age live together they are sent to reformatories for from one to three years. The law prescribes that if a man abandons those who are dependent on his support by reason of marriage or parental obligation he is liable to punishment ranging from three months to one year in prison. The same punishment is given the husband who does not pay his alimony for three successive months.

The new code contains severe measures against abortion, which offense is punished with imprisonment of from two to five years if done without the woman's consent. If she is taken ill in consequence of the operation or becomes incapacitated, the punishment is imprisonment ranging from three to six years and, if she dies, from seven to ten years. If the operation is performed by a single woman on herself or if she gives her consent to somebody else to have the operation performed on her, she is liable to from three to six months in prison; if she is married, from six to twelve months. The law does not punish artificial abortion if it is performed by a physician in case the life of the woman is in imminent danger or if pregnancy aggravates some disease to such an extent that her life is endangered and this danger cannot be averted in any other way but by the interruption of gestation. However, in such instances the physician is obliged to make a confidential notification to the public prosecutor within forty-eight hours. In other cases the operation can be performed only with the permission of the attorney's office on the ground of a preliminary medical consultation by at least two duly qualified physicians. The prosecutor's office is obliged to observe the confidential character of the notification.

An interesting section of the new code is that which states that if a physician kills one on his own request or entreaty, even if an aged person who wished to die to get rid of suffering, the act is regarded as manslaughter and is punished with imprisonment ranging from three to eight years.

The new penal code will come in force by Jan. 1, 1937.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Dec. 26, 1936.

#### Antigas Preparations

The extent of the preparations being made by the government against air raids on this country are not encouraging to those who hope for European peace. The latest is the issue by the Air Raids Precautions Department of a circular to local authorities outlining the scheme of antigas instruction for medical, dental and veterinary practitioners, students and nurses. The circular emphasizes the importance of bringing it about that physicians are conversant with antigas measures not only from the point of view of securing skilled treatment of gas casualties but also for the moral effect in enabling the public to look on their medical advisers as qualified to assist and advise in case of need. Accordingly fourteen physicians have been trained at the Civilian Anti-Gas School for the purpose of giving instruction to the medical, dental, veterinary and nursing professions. These physicians will be stationed at different towns, in which and in the areas around they will give instruction. By arrangement with the British Medical Association its branches will be used for organizing local courses for physicians, who will not be limited to members of the association. Arrangements for instruction at medical schools (where this is not given by a member of the staff) are being made with the deans. The College of Nursing is collaborating with regard to nurses.

The scheme for medical training has thus been devised without imposing any burden on local authorities either financially or in the matter of organization. The secretary of state is satisfied that the arrangements made will best suit the convenience of the physicians whom it is desired to reach. He is pleased to announce that the response which has already been made is such as to secure success. The equipment also is being provided by the department, and the only cost to be met locally will be that (if any) for accommodation for the local course and minor office expenses of organization. To meet this it is proposed that a small enrolment fee should be charged to those who attend the courses.

A forty-page booklet is being issued to the people in millions, instructing them to choose a refuge room—a room from which gases can be excluded. For rooms of normal height (8 to 9 feet) an allowance of 20 square feet of floor for each person will allow occupation with safety for twelve hours without ventilation. Thus a room 10 feet long and 10 feet wide will be adequate for five people for twelve hours. The occupants are advised to take in candles, matches, clean rags, tins or jars with air-tight lids for storing food, a screen for privacy, sanitary conveniences, water for drinking, and canned foods. For fire extinguishing, a box of sand with a shovel should be provided. "Never pour water on an incendiary bomb," they are told. "If there is an outbreak of fire, send for the fire department or inform the police."

#### The Services of the Voluntary Hospitals

In these days of vast state expenditure on public health, including municipal hospitals, it is impressive to consider the services of the voluntary hospitals (hospitals supported by the voluntary contributions of the charitable). At the Public Health Congress Lieut.-Col. Walter Parkes, house governor of St. Mary's Hospital, London, gave an address in which he stated that the expenditure of the voluntary hospitals in this country amounted annually to \$60,000,000. Voluntary hospitals were not the spoiled darlings of the state but stood or fell on their merits. Numerous acts of parliament took advan-

tage of the voluntary hospitals to make their schemes workable. Were it not for institutional treatment provided by the voluntary hospitals, national health insurance would break down. But for the treatment provided for highway accidents the government would have to provide a system of ambulance stations costing many millions of pounds. In recognition of this fact the state provided the hospitals with an act difficult to interpret, from which they might, if lucky, recover between a half and a third of the cost of the treatment given. In the matter of workmen's compensation (for injuries), the claims of all were covered except those of the voluntary hospitals. Public authorities were empowered to subscribe to voluntary hospitals. If full advantage were taken of this power, \$7,500,000 would be available, but the amount provided was only \$150,000. The country depended largely on the voluntary hospitals for the supply of nurses, toward whose education the state contributed nothing.

#### Surgeon Not Responsible for Error of Nurse

Attempts are made from time to time to make a surgeon responsible for the error of a nurse or assistant during an operation, but they have failed because it has been held that in the legal sense these persons are not his agents. The most recent case occurred in New Zealand and was due to an unusual cause. A woman claimed damages against a surgeon for injuries received during an operation in a private hospital. The nurse was instructed to paint the patient's skin with iodine but used a mixture containing phenol (carbolic acid). The New Zealand Court of Appeal, in giving judgment, said that the plaintiff's submission would impose an intolerable burden on the surgeon. Under the conditions of modern surgery it was impossible for the surgeon to do the whole of the work involved in an abdominal operation. He had to work in a team. It was true that he was in complete control, but those subject to him were skilled collaborators with independent duties and there was no delegation of duties in the ordinary sense. He did not intend and could not be taken to have intended to do the work of others in the team. He was not vicariously liable for negligence found against the nurse.

#### Cancer Research

At a meeting of the committee of the Imperial Cancer Research Fund, important recent research work was described.

##### THE STUDY OF VIRUSES

Dr. W. E. Gye, the director, said that when its laboratories were constructed twenty-five years ago the technic of cancer research was comparatively simple. During the last fifteen years the scope of research had widened enormously. The chemist working with the biologist was transforming the situation. The study of viruses was now one of the most important branches of their work and had almost become a science in itself. The Medical Research Council was going to build a new institute of chemotherapy which would be adjacent to the fund's new laboratories and they hoped to work in close cooperation. Their plans were largely to develop chemical work and the study of viruses. Some one might make an observation that would enable them to attack the problem from a new line.

##### THE PRODUCTION OF SARCOMA BY THORIUM DIOXIDE SOL

Dr. Gye commented on the experimental production of sarcoma by thorium dioxide sol, a colloidal solution of thorium dioxide, by Dr. F. R. Selbie of Middlesex Hospital. He said that mesothorium and radiothorium, two of the disintegration products of thorium dioxide, are constituents of the luminous paints, which have been shown capable of producing malignant tumors in man. Experimental observations with thorium dioxide sol and past experience with luminous paints lead to

**Charles Magill Fauntleroy** ☉ Medical Director, U. S. Public Health Service, Charleston, S. C.; University of Virginia Department of Medicine, Charlottesville, 1906; for many years in the U. S. Public Health Service; aged 55; died, Dec. 3, 1936.

**Rocco Brindisi** ☉ Boston; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1884; at one time Italian consul; formerly served on the United States federal education board; aged 76; died suddenly, Dec. 14, 1936, of heart disease.

**Arthur Patterson Chadbourne**, Washington, D. C.; Harvard University Medical School, Boston, 1888; member of the Massachusetts Medical Society; formerly connected with the Veterans Administration Facility; aged 73; died, Dec. 2, 1936.

**Charles Herbert Golden**, Wonevot, Wis.; Rush Medical College, Chicago, 1892; member of the State Medical Society of Wisconsin; aged 67; died, Nov. 3, 1936, as the result of a gunshot wound of the spine accidentally incurred while hunting.

**Francis Ambrose Harlow**, Bremerton, Wash.; Northwestern Medical College, St. Joseph, 1890; Cooper Medical College, San Francisco, 1895; formerly mayor; aged 74; died, Nov. 22, 1936, of arteriosclerosis and cardiac decompensation.

**Harold Le Roy Avery**, Primghar, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; member of the Iowa State Medical Society; aged 56; died, Dec. 6, 1936, in Pasadena, Calif.

**William Edson Baker**, Bucyrus, Ohio; Starling Medical College, Columbus, 1895; member of the Ohio State Medical Association; on the staff of the Bucyrus City Hospital; aged 71; died, Dec. 5, 1936, of heart disease.

**Stephen Henry Abbate**, Middletown, N. Y.; New York Homeopathic Medical College and Flower Hospital, 1929; on the staff of the Middletown State Homeopathic Hospital; aged 32; died, Dec. 15, 1936, of pneumonia.

**William Stephen Buckley** ☉ Boston; Harvard University Medical School, Boston, 1902; served during the World War; on the staff of St. Elizabeth's Hospital; aged 58; died, Dec. 8, 1936, of cerebral hemorrhage.

**John Harold Philip**, San Francisco; Bellevue Hospital Medical College, New York, 1895; aged 80; died, Nov. 22, 1936, in the Stanford Hospital, of acute bilateral pyelonephritis and acute myocarditis.

**Adelbert A. Taylor**, Washington, D. C.; George Washington University School of Medicine, Washington, 1900; aged 67; died, Nov. 1, 1936, in the Atlantic City (N. J.) Hospital, of chronic myocarditis.

**Coleman Carter**, Dallas, Texas; Kentucky School of Medicine, Louisville, 1885; for many years health officer of Leon County; aged 76; died, Nov. 29, 1936, in a local hospital, of cerebral hemorrhage.

**Anna G. Hilke Willard**, New Rochelle, N. Y.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1884; aged 76; died, Nov. 25, 1936, of coronary thrombosis.

**Hugh Campbell Cameron**, Johnstown, Neb.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1900; aged 60; died, Nov. 12, 1936, in the Ainsworth (Neb.) Hospital, of nephritis.

**Joseph Robert McQuaid**, Leetsdale, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1890; member of the Medical Society of the State of Pennsylvania; aged 74; died, Nov. 20, 1936.

**Harry M. Sigal** ☉ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1905; aged 50; died, Nov. 7, 1936, in the Montefiore Hospital of coronary thrombosis and chronic myocarditis.

**Frank Edmund Donelan**, Glenwood, Iowa; Ensworth Medical College, St. Joseph, Mo., 1890; aged 70; died, Nov. 28, 1936, in Monrovia, Calif., of prostatectomy and cerebral embolism.

**Coburn Badgley**, Fayetteville, N. Y.; Chicago Homeopathic Medical College, 1885; president of the board of education of Fayetteville; at one time village president; aged 78; died, Dec. 17, 1936.

**Arthur T. Barnum**, Toledo, Ohio; Chicago Homeopathic Medical College, 1890; honorary member of the Toledo Hospital; aged 70; died suddenly, Dec. 15, 1936, of diabetes mellitus.

**Jay Lee Cecil**, Armstrong, Mo.; Cleveland Homeopathic Medical College, 1899; aged 62; died, Dec. 18, 1936, in a hospital at Kansas City, following an operation for removal of a kidney.

**John F. Bunton**, Fredonia, Ky.; University of Louisville Medical Department, 1889; aged 73; died, Dec. 11, 1936, in the Welborn-Walker Hospital, Evansville, Ind., of prostatic hypertrophy.

**William W. S. Butler Sr.**, Roanoke, Va.; University of Maryland School of Medicine, Baltimore, 1881; aged 76; died, Dec. 15, 1936, in the Jefferson Hospital, of myocarditis and uremia.

**Mary Jamieson Coon**, Parsippany, Troy Hills, N. J.; Woman's Medical College of Pennsylvania, Philadelphia, 1883; aged 71; died, Nov. 29, 1936, of empyema and abscess of the lung.

**Daniel Oscar Webster** ☉ Portland, Ore.; Boston University School of Medicine, 1903; aged 60; died, Nov. 29, 1936, in a local hospital, of bronchopneumonia and renal calculi.

**Richard D. Harral**, Honey Grove, Texas; University of Louisville (Ky.) Medical Department, 1890; aged 72; died, Nov. 24, 1936, in Paris, of carcinoma of the lung.

**Egbert James Bailey**, New York; University of Vermont College of Medicine, Burlington, 1926; aged 42; was found dead, Dec. 21, 1936, of pulmonary tuberculosis.

**Ernest William De Long**, Los Angeles; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1904; aged 61; died, Nov. 19, 1936, of leukemia.

**David Mitchell Blum** ☉ Des Moines, Iowa; Rush Medical College, Chicago, 1922; aged 38; died, Dec. 13, 1936, of cerebral hemorrhage and malignant hypertension.

**Cyril Danilovitch Billik** ☉ New York; Rush Medical College, Chicago, 1917; aged 50; died suddenly, Dec. 8, 1936, of coronary thrombosis and arteriosclerosis.

**Fred Wendell Lovejoy**, East Pepperell, Mass.; University of Vermont College of Medicine, Burlington, 1884; aged 76; died, Nov. 25, 1936, of cerebral hemorrhage.

**George McCullagh**, Goodrich, N. D.; Medical Department of Hamline University, Minneapolis, 1903; aged 70; died, Nov. 24, 1936, of acute cardiac dilatation.

**Harvey R. Cronk**, New York; College of Physicians and Surgeons of Chicago, 1889; aged 76; died, Nov. 24, 1936, of carcinoma of the prostate and liver.

**John Byron Sloane**, Los Angeles; Detroit College of Medicine, 1893; aged 70; died, Nov. 28, 1936, in the Hollywood Hospital, of a cerebral hemorrhage.

**Andrew Leight Monroe**, River Junction, Fla.; Hahnemann Medical College of Philadelphia, 1879; aged 80; died, Nov. 17, 1936, of hypertensive heart disease.

**Ulysses Sidney Chapman**, Joplin, Mo.; Beaumont Hospital Medical College, St. Louis, 1892; aged 73; died, Dec. 15, 1936, of intestinal obstruction.

**Hiram Russell Palmer**, Oakland, Calif.; Fort Wayne (Ind.) College of Medicine, 1882; aged 80; died, Nov. 15, 1936, of carcinoma of the prostate.

**Harvey E. Brown**, Seneca Falls, N. Y.; University of Buffalo School of Medicine, 1887; aged 70; died, Dec. 31, 1936, of heart disease.

**Louis James Palmer**, Boston; Tufts College Medical School, Boston, 1906; aged 56; died, Nov. 21, 1936, of carcinoma of the lungs.

**Richard V. Mattison**, Ambler, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1879; aged 82; died, Nov. 18, 1936.

**William Wesley Cook**, Chicago; Physio-Medical Institute, Cincinnati, 1882; aged 77; died, Dec. 28, 1936, of influenza and lobar pneumonia.

**Henry Avery Doyle**, Phoenix, Ariz.; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; aged 83; died, Nov. 7, 1936.

**Joseph Milton Curtis**, Tecumseh, Neb.; Omaha Medical College, 1894; aged 70; died, Nov. 26, 1936, of coronary thrombosis.

**James M. Cooper**, Rockwell City, Iowa (licensed in 1882 in 1886); aged 83; died, Nov. 14, 1936, of carcinoma of the antrum.

**Harry C. Smith**, Hawthorne, Calif.; University Medical College of Kansas, Mo., 1903; aged 69; died, Nov. 14, 1936.

**Erico Arnaldo Scalzilli**, Medford, Mass. (licensed in Massachusetts in 1902); died, Nov. 21, 1936, in Malden.

**Gabriel Samter**, Detroit; Detroit College of Medicine, 1895; aged 69; died, Nov. 21, 1936, of myocarditis.

**Martha F. Caul**, Brooklyn; University of Buffalo School of Medicine, 1891; aged 68; died, Dec. 7, 1936.

pelvis and calices has taken place. Ectopic ending of the ureter in the female and its discovery through urologic study of every case of incontinence was especially mentioned. In the discussion, Dossot of Paris stated that in cases of extravescical (ectopic) ending of the ureter, if the ureter arises from half of a double kidney, a heminephrectomy is advisable, whereas if the kidney is a single one a nephrectomy should be done, since the ureter and the renal pelvis are infected in nearly every case. Lepoutre of Lille said that with the routine employment of intravenous urography many anomalies of the upper urinary tract could be found which otherwise escaped detection.

Of the other papers and demonstrations presented at this congress, the following deserve mention:

Films showing the expulsion of the contents of the renal pelvis into the ureter and those of the bladder into the urethra, by Drs. Stobbaerts and Van de Maele of Brussels, Belgium.

Cutaneous manifestations of *B. coli* infections of the urinary tract by Dr. Strominger of Bucharest, Rumania, who cited two cases of recurrent urticaria of five years' duration which were cured only after anticolibacillary treatment.

Value of radiography in upright position in diagnosis of nephralgia due to unsuspected movable kidney, by Dr. Perrin of Lyons.

Rôle of congenital anomalies of the kidneys and ureter as the cause of surgical conditions, by Dr. Robert Gutierrez of New York.

Indications for prostatic resection, by Dr. Bernard Fey of Paris. He said that, when there is but little residual urine but difficulty in urination and a trabeculated bladder, a transurethral resection is preferable to an ordinary prostatectomy.

#### **Tuberculous Bacillema in Erythema Nodosum**

The question as to whether there is a direct etiologic relation between erythema nodosum and tuberculosis is being studied here by Debré, Saenz and Broca. Hildebrand in 1907 was the first to find tubercle bacilli in the blood of erythema nodosum patients. Few reports have been published since that time which are above criticism from the bacteriologic point of view. This rarity of proved cases of tuberculous bacillema in erythema nodosum does not conflict with the belief of the authors that this skin disease is of tuberculous origin. It is known that a tuberculous bacillema is of short duration after inoculation of animals with virulent bacilli, whether by the subcutaneous, intraperitoneal or alimentary routes. The authors studied twenty-nine cases of erythema nodosum in order to determine the incidence of tuberculous bacillema in such cases and had only five positive results. Their report was presented at the July 7 meeting of the Académie de médecine. The blood specimen was always taken at the onset of the eruption and fever. In the five positive cases, from 10 to 15 cc. of blood was secured under aseptic precautions and coagulation prevented by the addition of 2 cc. of 5 per cent sodium citrate solution. The blood thus obtained was always found in its behavior toward the inoculated guinea-pigs as containing few bacilli; i. e., a long antiallergic period and a slow tuberculinization of the animals. In three cases the guinea-pigs reacted to tuberculin from sixty to sixty-five days, in one, seventy-two days and in another ninety-five days after inoculation. The animals usually died in from five to seven months, but in one case ten months after inoculation, showing a generalized tuberculosis with a typical lesion at the point of inoculation, regional lymph node enlargements and visceral changes. Three of the five children who had a positive blood culture had a positive skin reaction on admission to the hospital. In the fourth child the reaction was doubtful on admission but markedly positive four days later. In the fifth case it became positive seven months after appearance of the erythema nodosum. The proportion of positive cases, five of twenty-nine, or 17 per cent, is remarkably high, when one considers that the percentage of

positive cases reported and verified according to modern criteria has been only 3 or 4 per cent. The presence of a tuberculous bacillema is of no importance so far as the prognosis of the erythema nodosum is concerned. The bacillema is of only transitory character.

#### **Necrosis of Jaws Following Use of Radioactive Salts**

At the October 14 meeting of the Académie de médecine, Dechaume, stomatologist in the Paris public hospitals, reported three cases of necrosis of the jaws following the internal use of radioactive salts for chronic rheumatism. The chief danger of the injection of radioactive salts is their cumulative action. This is especially true of thorium and mesothorium salts, which have an elective affinity for the reticulo-endothelial tissue, especially that of the blood-forming organs (liver, spleen and bone marrow). Some individuals appear to store up the salts in the osseous structures. The chief danger of internal curietherapy is the length of time that can elapse between the end of the treatment and the appearance of the first clinical symptoms. There is much variation in this accumulation in individual patients, some tolerating relatively large doses and vice versa. No diagnostic method exists as yet which yields any information as to the degree of accumulation. The jaws are more commonly involved than any other bones. The onset is very insidious, so that the lesions are often well developed when the patient is first seen. The striking feature of Dechaume's three cases was a marked anemia. Intervention should be restricted to treatment of the accompanying infection. No treatment is of avail at present to accelerate the elimination or to neutralize the radioactive salts. F. B. Flinn (*THE JOURNAL*, May 23, 1931, p. 1763) has recommended the use of viosterol as an accelerator of elimination of the radium salts.

In the discussion, Moulouguet stated that the diagnosis of radionecrosis of the jaws is difficult. He had occasion to treat a patient in whom Dechaume had made this diagnosis, because the patient had been given several series of injections of mesothorium. A search for actinomycosis as the cause of the necrosis was at first negative but later positive. Antoine Bécclère called attention to the dangers of the use of radioactive salts either as a diagnostic method such as arteriography or as a therapeutic measure. There was, primarily, danger of bone involvement and, secondarily, of the development of osteosarcoma. At the request of Professor Duval, the academy appointed a committee to formulate the present status of the use of radioactive salts in injections.

#### **Infection of Intramural Origin in Children's Hospitals**

At the October 12 meeting of the Académie de médecine, Robert Debré stated that in spite of the noteworthy improvements in preventing contact infection during recent years, contagion still finds its way into children's hospitals or such services in general hospitals. The institution of the cubicle system, disinfection of the hands of physicians, wearing of blouses and face masks and similar precautions have not sufficed to prevent the bringing in of infectious diseases. Debré made a plea for a special intern who will examine every newly admitted patient and determine the contagious diseases against which the child is more or less completely immunized by a previous attack or as the result of vaccination, and those diseases toward which the child is particularly receptive. This intern should follow the cases as admitted to the observation wards when the diagnosis is doubtful, as well as to the wards for those in which a definite diagnosis could be made on admission. Having thus determined the potentially or actually contagious cases, the intern will immediately immunize children who are receptive by supplementary injection of anatoxin and serum of convalescents from measles, scarlatina, whooping cough and mumps. Debré has succeeded, as the result of the employment of such a special intern in his service at the Herold

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### CALORIES CONSUMED IN WALKING ONE MILE

To the Editor:—How many calories does a man of 175 pounds (80 Kg.) and/or a woman of 125 pounds (57 Kg.) consume in walking gently a mile? Please omit name. M.D., Illinois.

ANSWER.—A man of 175 pounds would give off 95 calories in walking one mile in twenty minutes, and a 125 pound woman would give off 70 calories in walking the same distance in the same time. Roughly speaking, about one third of the calories would be required for standing quietly, not walking, and the extra two thirds would be that required for the energy of walking itself. Thus, in the case of the man it would be 30.3 calories for standing quietly and 63.88 calories for the extra effort of walking. These figures are assuming that the person is post-absorptive, that is, that there is no active digestion going on, in which case there would be a slight increase over these figures.

### SKIN TEST FOR PREGNANCY

To the Editor:—Just recently I was told by one of the drug salesmen calling on me that there is a simple test for pregnancy. He further described this test saying to inject 0.2 cc. of antuitrin-S intracutaneously and wait thirty minutes to take the reading. If a reaction appears (red areola) at the site of injection the patient is not pregnant; if no reaction appears, she is pregnant. This test is supposed to be 95 per cent accurate and to be worth using after one missed period. Is this test really what it is claimed to be.

GORDON LAWYER, M.D., Cambridge, Ohio.

ANSWER.—The skin test for pregnancy consists in injecting 0.2 cc. of a preparation containing the gonadotropic principle from the urine of pregnancy into the skin and later noting the reaction around the site of the injection. If an erythema occurs the patient is assumed not to be pregnant; if no erythema occurs the patient is supposed to be pregnant. This test is based on the assumption that the pregnant woman, whose body fluids contain large quantities of the gonadotropic principle, would be "immune" to this substance whereas the non-pregnant woman would not be "immune."

This alleged pregnancy test has been known for at least eight years. It was apparently first proposed in 1929 by Porges and Pollatschek of Vienna (*THE JOURNAL*, Aug. 17, 1929, p. 559). It was subsequently investigated by Alfred Deutsch (*Zentralbl. f. Gynäk.* 53:2920 [Nov. 16] 1929) in Europe and by Hyman Strauss (*Am. J. Surg.* 8:1271 [June] 1930; *THE JOURNAL*, Sept. 24, 1934, p. 1015) in this country; both these workers found the test to be quite unreliable. Porges and Pollatschek themselves later reported a high incidence of diagnostic error in using their test (cf. Strauss).

Despite these previous reports, this "skin test" for pregnancy has twice been resurrected (Dowell, D. M.: *J. Missouri M. A.* 30:275 [July] 1933; *THE JOURNAL*, Aug. 18, 1934, p. 510. Gilfillen, G. C., and Gregg, W. K.: *Am. J. Obst. & Gynec.* 32:498 [Sept.] 1936). There is as yet no reason to believe that the test is any more reliable now than it was in 1929.

### HEALING OF SINUS AFTER NEPHRECTOMY

To the Editor:—Kindly discuss means of expediting healing of a post-operative sinus following nephrectomy for unilateral tuberculosis of the kidney. Kindly omit name and address. M.D., New York.

ANSWER.—A postoperative sinus following nephrectomy for renal tuberculosis frequently persists over a period of several months. This is nothing to be alarmed about, since infection in the perirenal tissues may retard healing. If drainage persists longer than this, however, some complication may be present and various therapeutic measures might be tried to expedite healing.

Tuberculosis itself does not cause much drainage. As a rule a persisting sinus is due to secondary infection, and a bacteriologic study of the secretion from the sinus might well be indicated. If secondary infection is present, injections of a stabilized form of diluted solution of sodium hypochlorite in a solution of 1:20 might be tried. Two or three cubic centimeters of this solution should be injected through a catheter inserted

into the sinus tract and repeated every hour or two during the day for several weeks. Flushing of the wound with hypertonic saline solution may also be of value.

Sometimes on investigation of the wound an undermining or pocket may be found along the anterior wall, which may require adequate drainage. If such a pocket is suspected, a roentgenogram made after injecting any radiopaque substance, such as neo-iopax or hippuran, into the sinus will reveal its presence. In rare cases a patent ureter permits passage of urine from the bladder into a persisting sinus and a complete ureterectomy may be indicated. Renal tissue remaining after incomplete nephrectomy may also cause a persisting sinus.

Heliotherapy is by far the best aid to closure of noncomplicated wounds. Exposure to the sun's rays in gradually increasing dosage, care being taken not to irritate the wound or the skin around it, has hastened healing in many persisting sinus tracts. Although this treatment may be carried out in the summer time in any part of the country, the sun's rays in a dry climate such as that of Arizona give the best results. Heliotherapy by means of lamps is not as efficacious but has been used with some success.

### CARBON MONOXIDE POISONING

To the Editor:—I have a group of questions to ask with regard to the physical and chemical observations of the blood in the postmortem examination in a case of suspected carbon monoxide poisoning (gas from exhaust pipe): 1. What is the general appearance of the skin? 2. Will the skin maintain this uniform general color throughout the body or will the color change materially in time? 3. Is there any difference in the length of time of decomposition between the carbon monoxide poisoning case and a case of death from natural causes? 4. Could there be a post-mortem examination done four or five weeks following internment to determine whether such a case was carbon monoxide poisoning? 5. What are the medicolegal tests for carbon monoxide poisoning? 6. Would sodium citrate added to postmortem blood of suspected carbon monoxide poisoning, taken about four hours following death, interfere with subsequent chemical or spectroscopic examination? 7. If a person was comatose from opiates, barbiturates or bromides, would a sufficient amount of carbon monoxide be absorbed by the blood to be tested subsequently? I would appreciate very much an early reply. Please omit name.

M.D., South Dakota.

ANSWER.—1. When the blood is well saturated with carbon monoxide the skin becomes cherry red; in the dependent parts the color may be a deeper red.

2. The skin may retain the color as described for a considerable time, it is said even for weeks and months.

3. No.

4. Yes. Carbon monoxide poisoning can be detected on post-mortem examination from four to five weeks after death. The blood may retain its redness even longer and carbon monoxide may be detected chemically and spectroscopically months after death.

5. Chemical tests (Katayama's, Hoppe-Seyler's and other tests) and spectroscopic examination.

6. No.

7. Yes; the conditions mentioned would not interfere with the absorption of carbon monoxide if it is present in the air that is inhaled.

### IRRITATING FUMES FROM HOT MOIST PAPER

To the Editor:—A patient of mine eight months ago bought a few carloads of paper wet in the Pittsburgh flood. He and his employees who unloaded the cars were subjected to irritating fumes and all developed painful intranasal swelling and irritation. The others recovered promptly. The man has had what he calls sinus headache much of the time since. He has been to half a dozen good nose and throat men without real relief. The sinus x-ray report is not informative. There is no history of allergy. Is there any reason to suppose that irritating fumes from hot moist paper could produce such persistent trouble?

LOVETT DEWEES, M.D., Ardmore, Pa.

ANSWER.—Although this query fails to provide full facts as to the type of paper, it is within reason to believe that the paper probably was of the Kraft variety and therefore contained sulfites or chemical compounds formed from sulfites. The wetting process would tend to enhance the production of sulfurous or sulfuric acid. This type of complaint is at present emanating from various newspaper pressrooms where paper dust containing sulfites or sulfur acids are proving to be sources of irritation to the upper respiratory tract. The claim is being made that tuberculosis is becoming of higher incidence among pressmen on this account. The latter claim perhaps is unwarranted and at least is unproved. Low grade irritation, however, is an actuality in some instances. A somewhat analogous situation undoubtedly was created in connection with carloads of moist paper. Although acids, such as sulfuric, do not readily evaporate, irritant vapors no less enter the atmosphere, and

of all persons receiving the license to practice medicine were women (324 women in a total of 2,109 persons licensed); of students who passed the preliminary examination in medicine (given at the end of the first five semesters of study) 22.1 per cent were women; at the same time 19.8 per cent of all medical students were women. The total number of licenses granted underwent a sharp increase in 1933-1934 (2,109 persons licensed as against 1,280 in 1932-1933). On the other hand there was but a slight increase in the number of students who passed the preliminary examination (4,943 in 1933-1934 against 4,836 in 1932-1933) and, throughout, the increase in the number of

TABLE 2.—Increase in Number of Heilpraktiker Prior to 1935

Year	Number of Heilpraktiker	Number of Women Heilpraktiker	Heilpraktiker per 10,000 of Population	Heilpraktiker to Each Ten Physicians
1876	670	95	0.16	0.49
1887	1,713	305	0.36	1.08
1898	3,059	766	0.56	1.24
1909	4,468	1,322	0.70	1.46
1927	11,761	2,832	1.86	2.70
1928	12,098	2,803	1.90	2.63
1929	12,413	3,091	1.94	2.61
1930	12,942	3,094	2.01	2.74
1931	14,031	3,372	2.17	2.93
1934	14,266	3,378	2.19	3.02
1935	14,023	3,359	2.13	2.96

women was considerably greater than the increase in the number of men. Conversely, the total number of medical students declined, although the number of women students declined at a slower rate than that of the men students. The statistics on the distribution of medical students over various semesters show that the high figures for those entering the medical profession will remain about the same for some three years and then will suddenly drop to about one half their former value. How long the number of new admissions will remain at so low a level cannot be computed beforehand, since the exigencies of the work service and military service are factors conducive to a retrogression in the number of students admitted to the medical schools. On the other hand, the decline in the number of women matriculants is so considerable that it cannot alone be attributed to the work service but may be taken to indicate that fewer women contemplate medicine as a career. Whereas the number of matriculants in medicine amounted in 1933-1934 to 2,866 men and 852 women, corresponding figures for 1934-1935 show only 1,826 men and 338 women or, in terms of percentage of the matriculants in the preceding academic year, only 65 per cent and 39.7 per cent for men and women respectively. The number of specializing physicians Jan. 1, 1935, showed an increase of 1 per cent. over Jan. 1, 1934. The greatest increase was among the internists, whereas the greatest decrease was among the dermatologists and venereologists. The proportion of women is by far the highest among pediatricians and lowest among surgeons and otorhinolaryngologists. Table 1 shows in detail the distribution of physicians engaged in the specialties.

It is further estimated that 4 per cent of physicians were in government service and 17 per cent were occupying permanent posts in institutions for the sick. Only one half of all physicians had selected to exercise their profession in a general, independent, nonspecialized practice. Detailed statistics on the groups lying outside regular medicine are of scant interest with the exception of the figures for the "heilpraktiker." These lay practitioners occupied a more favorable position under the new régime than that formerly enjoyed by them, a fact mentioned in previous letters. In this survey all unlicensed persons who were professionally engaged in the treatment of the sick were reckoned as "heilpraktiker." Jan. 1, 1935, there were three such heilpraktiker to each ten regular physicians in Germany; the corresponding ratio was 2.6:10 in 1929, 1.5:10 in 1909,

1.1:10 in 1878 and 0.5:10 in 1876. Sixty years ago there were only 670 heilpraktiker (according to the rather incomplete records of those times); today there are 14,023 such practitioners. The increase in the number of heilpraktiker took place at a greater rate than the increase in the number of regular physicians until 1927 and has made yet further advances since that time. In 1935 a decrease is to be noted for the first time, presumably a consequence of the measures instituted for the "purgation" of the ranks of the lay practitioners. The increase in the number of heilpraktiker prior to 1935 is shown in table 2.

The proportion of women is higher among the heilpraktiker than among the physicians or the dental physicians. Before the war the proportion of women heilpraktiker had increased from 14 per cent to 30 per cent; after the war it remained with great regularity at around 24 per cent—not quite one fourth of the total. An explanation of the considerable proportion of women lay practitioners may be found in the fact that traditionally many farmers' wives and nurses of one sort or another, including women in holy orders and masseuses, were classed as heilpraktiker.

#### Recent Vital Statistics

According to Dr. Wagner, the national fuerhrer of physicians, an annual rate of twenty births per thousand of population is to be considered the desired goal. This objective was nearly attained in 1935, the rate for that year being 19.7 per thousand. But in the last quarter of the year a slump to 17.4 took place. Wagner explains this decrease by the fact that many young couples had just previously found it possible to marry with the aid of government subsidies, thus creating a decline in the number of the even more recently married. The foundation of new families, on the wane throughout the depression years, once more proceeds at a more nearly normal rate, thanks largely to state aid for couples contemplating marriage. The total number of marriages contracted in 1935 was 650,851; the living births in the same year numbered 1,261,273. Despite the renewed retrogression in the birth rate observable in the last three months of the year, the number of births in the entire year 1935 still represented an increase of 64,533 (5.4 per cent) over the year 1934 and was still some 30 per cent above the lowest point of 1933. The excess of births reached 469,361 and was therewith smaller by 2,713 than in 1934. The population of the German reich at the close of 1935 was 67,069,000. The easily studied data contained in the new German mortality table for 1932-1934 contain much that is of interest. The last previous German mortality table, that of 1924-1926, had shown an extraordinarily pronounced decline in the death rate. The new mortality table of 1932-1934 exhibits, after a lapse of eight years as it were, a further marked decline in the death rate among nearly all age groups; what is more important, the decline in infant mortality is particularly noteworthy. The death rate for infants in the first year of life has declined more than one fourth. The average 1932-1934 rate for male infants in the first year of life was 85.35 per thousand living births against 115.38 per thousand in 1924-1926. The corresponding rate for females was only 68.39 in 1932-1934 against 93.92 in 1924-1926. On the basis of the mortality statistics for 1932-1934 the mean expectation of life was 59.86 years for each male infant born alive. This represents an addition of four years to the expectation (55.97 years) based on the mortality table of 1924-1926 and is greater by fifteen years than a corresponding figure (41.82 years) based on the still earlier table covering 1901-1910. The expectation of life for female infants born alive is, on the basis of the table of 1932-1934, 62.75 years. This mean figure also represents a four year increase over the expectation according to the table of 1924-1926 and an increase of 14.4 years over a corresponding mean based on the table of 1901-1910. After due allowance is made for the excess of male infants over female infants (106.5 males to 100 females) the

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### CALORIES CONSUMED IN WALKING ONE MILE

To the Editor:—How many calories does a man of 175 pounds (80 Kg.) and/or a woman of 125 pounds (57 Kg.) consume in walking gently a mile? Please omit name. M.D., Illinois.

ANSWER.—A man of 175 pounds would give off 95 calories in walking one mile in twenty minutes, and a 125 pound woman would give off 70 calories in walking the same distance in the same time. Roughly speaking, about one third of the calories would be required for standing quietly, not walking, and the extra two thirds would be that required for the energy of walking itself. Thus, in the case of the man it would be 30.3 calories for standing quietly and 63.88 calories for the extra effort of walking. These figures are assuming that the person is post-absorptive, that is, that there is no active digestion going on, in which case there would be a slight increase over these figures.

### SKIN TEST FOR PREGNANCY

To the Editor:—Just recently I was told by one of the drug salesmen calling on me that there is a simple test for pregnancy. He further described this test saying to inject 0.2 cc. of antuitrin-S intracutaneously and wait thirty minutes to take the reading. If a reaction appears (red areola) at the site of injection the patient is not pregnant; if no reaction appears, she is pregnant. This test is supposed to be 95 per cent accurate and to be worth using after one missed period. Is this test really what it is claimed to be. GORDON LAWYER, M.D., Cambridge, Ohio.

ANSWER.—The skin test for pregnancy consists in injecting 0.2 cc. of a preparation containing the gonadotropic principle from the urine of pregnancy into the skin and later noting the reaction around the site of the injection. If an erythema occurs the patient is assumed not to be pregnant; if no erythema occurs the patient is supposed to be pregnant. This test is based on the assumption that the pregnant woman, whose body fluids contain large quantities of the gonadotropic principle, would be "immune" to this substance whereas the non-pregnant woman would not be "immune."

This alleged pregnancy test has been known for at least eight years. It was apparently first proposed in 1929 by Porges and Pollatschek of Vienna (*THE JOURNAL*, Aug. 17, 1929, p. 559). It was subsequently investigated by Alfred Deutsch (*Zentralbl. f. Gynäk.* 53:2920 [Nov. 16] 1929) in Europe and by Hyman Strauss (*Am. J. Surg.* 8:1271 [June] 1930; *THE JOURNAL*, Sept. 24, 1934, p. 1015) in this country; both these workers found the test to be quite unreliable. Porges and Pollatschek themselves later reported a high incidence of diagnostic error in using their test (cf. Strauss).

Despite these previous reports, this "skin test" for pregnancy has twice been resurrected (Dowell, D. M.: *J. Missouri M. A.* 30:275 [July] 1933; *THE JOURNAL*, Aug. 18, 1934, p. 510. Gilfillen, G. C., and Gregg, W. K.: *Am. J. Obst. & Gynec.* 32:498 [Sept.] 1936). There is as yet no reason to believe that the test is any more reliable now than it was in 1929.

### HEALING OF SINUS AFTER NEPHRECTOMY

To the Editor:—Kindly discuss means of expediting healing of a post-operative sinus following nephrectomy for unilateral tuberculosis of the kidney. Kindly omit name and address. M.D., New York.

ANSWER.—A postoperative sinus following nephrectomy for renal tuberculosis frequently persists over a period of several months. This is nothing to be alarmed about, since infection in the perirenal tissues may retard healing. If drainage persists longer than this, however, some complication may be present and various therapeutic measures might be tried to expedite healing.

Tuberculosis itself does not cause much drainage. As a rule a persisting sinus is due to secondary infection, and a bacteriologic study of the secretion from the sinus might well be indicated. If secondary infection is present, injections of a stabilized form of diluted solution of sodium hypochlorite in a solution of 1:20 might be tried. Two or three cubic centimeters of this solution should be injected through a catheter inserted

into the sinus tract and repeated every hour or two during the day for several weeks. Flushing of the wound with hypotonic saline solution may also be of value.

Sometimes on investigation of the wound an undermining pocket may be found along the anterior wall, which may require adequate drainage. If such a pocket is suspected, a roentgenogram made after injecting any radiopaque substance, such as neo-iopax or hippuran, into the sinus will reveal its presence. In rare cases a patent ureter permits passage of urine from the bladder into a persisting sinus and a complete ureterectomy may be indicated. Renal tissue remaining after incomplete nephrectomy may also cause a persisting sinus.

Heliotherapy is by far the best aid to closure of complicated wounds. Exposure to the sun's rays in gradually increasing dosage, care being taken not to irritate the wound or the skin around it, has hastened healing in many persisting sinus tracts. Although this treatment may be carried on in the summer time in any part of the country, the sun's rays in a dry climate such as that of Arizona give the best results. Heliotherapy by means of lamps is not as efficacious but has been used with some success.

### CARBON MONOXIDE POISONING

To the Editor:—I have a group of questions to ask with regard to the physical and chemical observations of the blood in the postmortem examination in a case of suspected carbon monoxide poisoning (gas from exhaust pipe): 1. What is the general appearance of the skin? 2. Will the skin maintain this uniform general color throughout the body or will the color change materially in time? 3. Is there any difference in the length of time of decomposition between the carbon monoxide poison case and a case of death from natural causes? 4. Could there be a post-mortem examination done four or five weeks following interment to determine whether such a case was carbon monoxide poisoning? 5. Why are the medicolegal tests for carbon monoxide poisoning? 6. Would sodium citrate added to postmortem blood of suspected carbon monoxide poisoning, taken about four hours following death, interfere with subsequent chemical or spectroscopic examination? 7. If a person was comatose from opiates, barbiturates or bromides, would a sufficient amount of carbon monoxide be absorbed by the blood to be tested subsequently? I would appreciate very much an early reply. Please omit name. M.D., South Dakota.

ANSWER.—1. When the blood is well saturated with carbon monoxide the skin becomes cherry red; in the dependent parts the color may be a deeper red.

2. The skin may retain the color as described for a considerable time, it is said even for weeks and months.

3. No.

4. Yes. Carbon monoxide poisoning can be detected on post-mortem examination from four to five weeks after death. The blood may retain its redness even longer and carbon monoxide may be detected chemically and spectroscopically months after death.

5. Chemical tests (Katayama's, Hoppe-Seyler's and other tests) and spectroscopic examination.

6. No.

7. Yes; the conditions mentioned would not interfere with the absorption of carbon monoxide if it is present in the air that is inhaled.

### IRRITATING FUMES FROM HOT MOIST PAPER

To the Editor:—A patient of mine eight months ago brought a few carloads of paper wet in the Pittsburgh flood. He and his employees who unloaded the cars were subjected to irritating fumes and all developed painful intranasal swelling and irritation. The others recovered promptly. The man has had what he calls sinus headache much of the time since. He has been to half a dozen good nose and throat men without real relief. The sinus x-ray report is not informative. There is no history of allergy. Is there any reason to suppose that irritating fumes from hot moist paper could produce such persistent trouble?

LOVETT DEWEES, M.D., Ardmore, Pa.

ANSWER.—Although this query fails to provide full facts as to the type of paper, it is within reason to believe that the paper probably was of the Kraft variety and therefore contained sulfites or chemical compounds formed from sulfites. The wetting process would tend to enhance the production of sulfurous or sulfuric acid. This type of complaint is at present emanating from various newspaper pressrooms where paper dust containing sulfites or sulfur acids are proving to be a source of irritation to the upper respiratory tract. The claim is being made that tuberculosis is becoming of higher incidence among pressmen on this account. The latter claim perhaps is unproven and at least is unproved. Low grade irritation, however, is an actuality in some instances. A somewhat analogous situation undoubtedly was created in connection with carloads of moist paper. Although acids, such as sulfuric, do not readily evaporate, irritant vapors no less enter the atmosphere and

## Marriages

JOSEPH B. GAIDA, St. Cloud, Minn., to Miss Naomi Mary Ann Aubin of Minneapolis, recently.

WILLIAM ALEXANDER GREENE to Miss Kayte Winesette, both of Whiteville, N. C., Oct. 17, 1936.

ROBERT BOONE OUTLAND, Elm City, N. C., to Miss Lois Griswold of Wendell, Nov. 5, 1936.

JOHN W. MAYHER to Miss Dorothy Shannan Illges, both of Columbus, Ga., Nov. 10, 1936.

JOHN A. BOOHER, Reedsburg, Wis., to Miss Esther Rooney of Baraboo, Sept. 26, 1936.

STUART B. GIBSON, Williamsport, Pa., to Miss Eleanor Orr of Baltimore, Oct. 16, 1936.

JOHN A. TASCHÉ JR. to Miss Myra Mueller, both of Sheboygan, Wis., Sept. 8, 1936.

RICHARD A. KINNEY, Jamestown, N. Y., to Miss Alice Mae Mink of Falconer, recently.

EDGAR M. SHAW to Miss Elizabeth Miller, both of Zwolle, La., Oct. 11, 1936.

## Deaths

Charles Franklin Adams ☉ Trenton, N. J.; Jefferson Medical College of Philadelphia, 1887; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; served during the World War; ophthalmologist to the Orthopedic Hospital, Trenton, and the New Jersey State Home for Boys, Jamesburg; chief of the department of ophthalmology and otolaryngology, and for many years secretary of the medical board of the Mercer Hospital; consultant in ophthalmology, State Hospital; consultant in ophthalmology and otolaryngology, Municipal Hospital, Trenton, and the New Jersey State Village for Epileptics, Skillman; aged 77; died, Dec. 14, 1936, of cerebral hemorrhage.

William Frederick Wegge ☉ Milwaukee; University of Maryland School of Medicine, Baltimore, 1886; clinical professor of neurology, emeritus, Marquette University School of Medicine; past president of the Milwaukee Neuro-Psychiatric Society; fellow of the American College of Physicians; served in various capacities on the staffs of the Milwaukee County General, St. Mary's, St. Joseph's and the Johnston Emergency hospitals; aged 73; died, Nov. 20, 1936, of coronary thrombosis.

George Henry Allen ☉ Topeka, Kan.; State University of Iowa College of Medicine, Iowa City, 1908; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; past president of the Shawnee County Medical Society; served during the World War; aged 56; on the staffs of the Hillcrest Sanatorium and the Jane C. Stormont Hospital, where he died, Dec. 18, 1936, of Hodgkin's disease.

Frederic de Kraft ☉ New York; Jefferson Medical College of Philadelphia, 1883; in 1932 was one of the eight physicians to receive the annual award of the American Congress of Physical Therapy for outstanding accomplishments in his field; past president of the American Electrotherapeutic Society; formerly on the board of consulting physicians of the Manhattan State Hospital; aged 75; died, Dec. 25, 1936, of pneumonia.

Thomas Francis O'Brien, Hartford, Conn.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1916; member of the Connecticut State Medical Society; served during the World War; health officer; formerly superintendent of The Seaside, Waterford; for many years on the staff of St. Francis Hospital; aged 52; died, Nov. 30, 1936, of nephritis.

John Smith Fogg, Biddeford, Maine; Medical School of Maine, Portland, 1891; Bellevue Hospital Medical College, New York, 1891; veteran of the Spanish-American War and the Philippine Insurrection and was discharged on account of physical disability incurred in line of duty; aged 71; died, Nov. 20, 1936, in the Veterans Administration Facility, New York.

Gavin Watson, Clarksville, Texas; Kentucky School of Medicine, Louisville, 1905; member of the State Medical Association of Texas; formerly secretary of the Red River County

Medical Society; county health officer; aged 54; died, Nov. 10, 1936, in a sanatorium at Paris, of pneumonia, following fracture of the femur and humerus received in a fall.

John Leo Chabot, Ottawa, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1892; fellow of the American College of Surgeons; formerly member of parliament; served during the World War; consulting surgeon to the Ottawa General Hospital and surgeon to the Ottawa Civic Hospital; aged 67; died, Dec. 8, 1936.

Frank Cook Abbott ☉ Philadelphia; Jefferson Medical College of Philadelphia, 1905; associate professor of general anatomy at the Temple University School of Dentistry; served during the World War; was on the courtesy staffs of several hospitals of Philadelphia, notably St. Joseph's Hospital; aged 58; died, Dec. 24, 1936.

George Alexander Bridge, Bisbee, Ariz.; Columbia University College of Physicians and Surgeons, New York, 1902; past president and treasurer of the Arizona State Medical Association; fellow of the American College of Surgeons; formerly on the staff of the Copper Queen Hospital; aged 63; died, Nov. 18, 1936.

Frederic Courtney Bishop ☉ New Haven, Conn.; Yale University School of Medicine, New Haven, 1895; president of the New Haven County Medical Society; formerly chief medical examiner in New Haven for the Metropolitan Life Insurance Company; aged 66; died, Dec. 22, 1936, of heart disease and coronary occlusion.

Herman S. Bowles, Muncie, Ind.; Medical College of Ohio, Cincinnati, 1902; past president of the Muncie Academy of Medicine; served during the World War; formerly county health officer; aged 59; on the staff of the Ball Memorial Hospital, where he died, Dec. 2, 1936, of tuberculosis.

Clarence Robertson Bass, Cimarron, N. M.; Kentucky University Medical Department, Louisville, 1902; member of the New Mexico Medical Society; aged 59; died in December 1936 at the New Mexico Miners Hospital, Raton, of injuries received in an automobile accident.

John Elisha Campbell, South St. Paul, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; member of the Minnesota State Medical Association; aged 61; died Nov. 24, 1936, in Inver Grove, of a skull fracture received in an automobile accident.

Jau Don Ball ☉ San Francisco; University of Virginia Department of Medicine, Charlottesville, 1902; member of the American Psychiatric Association; aged 56; died, Nov. 25, 1936, in St. Luke's Hospital, of cirrhosis of the liver, gastric hemorrhage and diabetes mellitus.

Grover Pierson Alton, Gashland, Mo.; Kansas City Medical College, 1898; member of the Missouri State Medical Association; served during the World War; aged 64; died, Dec. 16, 1936, in the Research Hospital, Kansas City, of arteriosclerotic cardiovascular disease.

Ingersoll Olmsted, Hamilton, Ontario, Canada; University of Toronto Faculty of Medicine, 1887; member of the American Surgical Association; fellow of the American College of Surgeons; surgeon to the Hamilton General Hospital; aged 72; died, Nov. 12, 1936.

Louis Dale Carman, New York; Howard University College of Medicine, Washington, D. C., 1888; Georgetown University School of Medicine, Washington, D. C., 1889; for many years medical examiner for the Pension Bureau; aged 76; died, Dec. 15, 1936.

Kent Oakley Brown ☉ Hartford, Conn.; Kansas Medical College, Topeka, 1902; chairman and medical member on the rating board of the Veterans Administration Facility, Newington; aged 66; died, Dec. 8, 1936, of coronary occlusion and arteriosclerosis.

Ethan Henry Smith, San Francisco; Bellevue Hospital Medical College, New York, 1889; formerly professor of orthopedic surgery, College of Physicians and Surgeons of San Francisco; on the staff of the French Hospital; aged 72; died, Nov. 24, 1936.

Walter Cayley Belt, Newport, Ore.; Trinity Medical College, Toronto, Ont., Canada, and Victoria University Medical Department, Coburg, Ont., 1892; served during the World War; aged 64; died, Dec. 22, 1936, in the Koloa Hospital, Koloa, Hawaii.

Alfred Clark Carpenter, Milford, Conn.; University of the City of New York Medical Department, 1889; member of the Connecticut State Medical Society; on the staff of the Milford Hospital; aged 70; died, Nov. 1, 1936, of coronary occlusion.

## CARR DRUG COMPANY

To the Editor:—I am looking for information in regard to the reliability of the "Carr Drug Company" of Muncie, Ind. Does your department of investigation have any information regarding the quality of drugs which they sell? The prices they quote are much lower than the ordinary companies offer but I do not want to buy inferior drugs. If you can advise me in this matter I would greatly appreciate it.

M.D., New York.

ANSWER.—No product of the Carr Drug Company stands accepted by the Council on Pharmacy and Chemistry. The inquirer need only look at a recent folder entitled "Special Introductory Prices on Tablets" to note the type of unscientific medicine promoted by this concern. For instance, "Aconite-Binioid Comp. Spec. (T. T.) was Follicular Tonsillitis" is stated to have the following composition:

Extract Cannabis	1/16 gr.
Tr. Aconite U. S. P.	5/16 gr.
Tr. Belladonna, U. S. P.	3/16 gr.
Tr. Bryonia	1/16 gr.
Mercuric Iodide Red	1/100 gr.
Sodium Salicylate	1 gr.
Wintergreen Flavor	q.s.

The phrase "was Follicular Tonsillitis" indicates that the firm has changed the name from one which is therapeutically suggestive to one which partly indicates the composition of this shot-gun mixture.

Or if a physician wishes an example of taking a good drug, phenobarbital, and surrounding it with unscientific pharmaceutical shrubbery there is the example of "Phenobarbital-Passiflora Comp. (S. C. Red)":

Phenobarbital	1/4 gr.
Ext. Passiflora Incarnata	1 gr.
Ext. Valerian	1 gr.
Ext. Sumbul	1/2 gr.
Ext. Hyoscyamus	1/2 gr.

Although the use of calcium sulfide and echinacea compounds has been considered therapeutically undesirable for many years, this firm promotes "Sulphides Comp. & Echinacea (S. C. White) was Acne (Dermatitis)" as having the following composition:

Calcium Sulfide	1/4 gr.
Arsenic Sulfide	1/100 gr.
Ext. Echinacea	1/2 gr.
Berberis	1 gr.
Nux Vomica	1/2 gr.
Juglandin	1/4 gr.

Many years ago the fallacy of treating rheumatism with lithium was exploded, yet in 1936 this firm presents to physicians "Lithium Salicylate Comp. was Rheumatic B-Yocum R." having the following declared formula:

Lithium Salicylate	5 gr.
Macrotin	1/4 gr.
Phytolaccin	1/2 gr.
Colchicine	1/150 gr.

Such prescriptions are an insult to the intelligence of the medical profession and suggest that the house is one of those the policies of which are inimical to the best interests of the public and the medical profession.

The Carr Drug Company is one of the firms which cater to those physicians who are still using the complex mixtures which were in general vogue more than twenty years ago. Many of these mixtures are not only marketed with unwarranted claims but are sold under names or subtitles which may lead physicians to use them uncritically. Therapeutically suggestive designations are an invitation to use the products without consideration of the component parts or the needs of the individual patient.

## FURUNCULOSIS

To the Editor:—There being such a galaxy of remedies in the treatment of furunculosis, most of them experimental, one is at a loss to know just what treatment to resort to. What in your opinion is the most recent effective therapy employed in combating furunculosis? I have tried stock vaccines, diet and hygienic measures with negative results. Please omit name.

M.D., South Carolina.

ANSWER.—To prevent recurrence of furuncles in an obstinate case demands local and systemic attack. The local treatment is essentially the maintenance of an extreme degree of cleanliness by dressing the furuncle so that its infectious discharge is not disseminated, and by washing the affected area with tincture of green soap and a flesh brush after the lesion has healed, followed by application of a hot towel, and finishing with a disinfectant lotion such as 2 per cent salicylic acid in 75 per cent alcohol. If the skin has a tendency to excessive sweating, a dusting powder (5 per cent salicylic acid in talcum) may be helpful. If this does not suffice, the affected region should be subjected to a series of five or six x-ray treatments (85 kilovolts, no filter, 75 reentens once a week).

The systemic treatment consists in correcting any existing impairment of nutrition, such as diabetes, nephritis, obesity or hypervitaminosis D. As resistance may be kept up by foci of infection, these should be removed. Resistance may be raised by the administration of autogenous vaccine, which should not be started until the acute lesion has disappeared. It should be given in gradually increasing doses to produce a definite but mild local reaction, and should be repeated at intervals sufficient to permit complete disappearance of all phenomena of reaction. This treatment should be continued until the patient can tolerate without reaction possibly ten times the dose that at first produced a reaction.

## TREATMENT OF CONVULSIVE DISORDER WITH OTHER

To the Editor:—A woman, aged 28, since February 1932 has had a slight purulent discharge from the right ear. An otologist states that in his opinion there is a low grade bone involvement in the attic and probably antral regions. X-ray examination shows both mastoids to be dense and sclerotic. Specialized testing showed normal cochlear and vestibular function in both ears. The upper part of the drum is perforated. In January 1932 she was in an automobile accident. She was unconscious for not more than one or two minutes. Since the ear trouble dates from one month later, she attributes it to the accident. In April 1933 she suffered an attack of what was diagnosed as idiopathic grand mal. A second attack occurred in July 1933, a third attack in August 1933 and a fourth attack in September 1934. There has been no attack since. All attacks were nocturnal, the patient herself being entirely unaware of anything happening until the spell was over. Cessation of the attacks since September 1934 have not been due to treatment as she has had none. However, before the first attack her ear was treated by instilling powders. This was continued several months. However, after the last spell, she changed otologists and the doctor avoided all local medication, merely wiping the canal dry as needed. I omitted to state that there was no history of previous convulsions; but on one occasion in girlhood her mother was unable to awaken her for school and she awoke only after a half hour of slapping and application of cold water to the face. Her hearing is not markedly affected. The infection in the ear seems to have changed since its onset. However, it is making her more and more neurotic and she fears another convulsion. Do you think the otitis could cause the convulsions she had? What do you think the prognosis of the otitis is? Could the automobile accident have caused either the otitis or the convulsions? On one occasion she "washed" her ear herself and became so dizzy that she was confined to bed for twelve hours. There have been no other dizzy spells. Laboratory examinations reveal red cells 4,700,000, hemoglobin 87 per cent, white cells 7,500, differential and morphology normal, urea nitrogen 14.2, uric acid 2.7, sugar 96, cholesterol 48.5, calcium 0.4, phosphates 3.4, cholesterol 200, carbon dioxide 22.1, platelets 430,000, coagulation time 5 seconds. The specific gravity of the urine is 1.036. The Mosenthal test reveals the lowest specific gravity 1.030, highest 1.037; the total day output is 423 cc. with 5.2 Gm. of chlorides; the total night output is 355 cc. with 1.3 Gm. of chlorides. The phenolsulfonphthalein test returned 97 per cent in two hours; total output 758 cc. with 6.5 Gm. of chlorides. The blood Wassermann reaction is negative. The spinal fluid Wassermann reaction is negative. The colloidal gold curve is 1111000000; globulin, negative; protein, 0.35 Gm. These have been reported as all normal, but don't you think the specific gravity of the urine is constantly high and the total output of urine and chlorides reduced? Would you please answer these questions: 1. How do the urinary observations any relation to convulsions (by upsetting the water balance)? 2. Do you think the otitis could cause the convulsions? 3. What treatment would you recommend for the ear? 4. What do you think the prognosis is? 5. Do you think the automobile trauma has any relation to the case? Please omit name.

M.D., New York.

ANSWER.—1. The specific gravity is unusually high and suggests that the patient may require fixation of fluid intake and regulation of diet. Normal adult fluid intake averages 30 ounces of liquid a day. Normal diet should contain from 20 to 30 ounces with a history of convulsive seizures. Liquid intake should not exceed 30 ounces a day and the diet should contain approximately 20 to 24 ounces of water content. Carbohydrate, starch and sugar consumption should be prevented and regulated. The fluid intake and output and the specific gravity of the urine should be recorded over a two week period to determine fluctuations. Under an appropriate diet the specific gravity should be reduced, if the patient's excretion does not involve excessive perspiration.

2. The otitis as described is not the cause of the convulsions.

3. The treatment for the chronic ear condition, in addition to the accepted local care, should include autogenous vaccine and a high vitamin diet.

4. The prognosis as to the convulsive seizures is favorable under strict and continued regulation of weight, diet, fluid intake and appropriate activities.

5. Posttraumatic epilepsy occurs in approximately 2 per cent of cerebral trauma. An encephalogram alone will not determine the cerebral disorder, which may be attributed to traumatic or inflammatory origin. The colloidal gold curve is also abnormal in the test should be repeated. In view of the early history of the test which suggests a possibility of an attack in childhood.

## Correspondence

### THROMBO-ANGIITIS OBLITERANS

*To the Editor:*—In *THE JOURNAL*, Dec. 12, 1936, Collens and Wilensky, cited a case of thrombo-angiitis obliterans, No. 3 in their series, which was apparently healed, according to the illustration on page 1961. On page 1965 the statement is made "Of all the ulcers that have healed in our series, not one has subsequently broken down."

It may be interesting to report that this patient, P. N., was examined at my office on Oct. 21, 1936, at which time there was an ulcer about 2 by 3 cm. in diameter on the stump of the left foot near the medial surface. According to the patient's statement, this ulcer had been present for a few weeks and showed no signs of healing although he has been using the Collens apparatus continuously. An oscillometric tracing taken on the same day showed no arterial pulsation whatever at the ankle level.

SAUL S. SAMUELS, M.D., New York.

### "SYPHILIS SIVE MORBUS HUMANUS"

*To the Editor:*—I have read with interest your review of Dr. Butler's book *Syphilis sive Morbus Humanus*. In this review appears the following:

However much one may be in sympathy with the contention of the author that syphilis did not originate in the New World, his array of historical evidence in this direction is far from convincing. The description of the venereal diseases by precolumbian physicians might apply to a half dozen diseases that could be easily confused with syphilis. Furthermore, the most authoritative of the postcolumbian writers, Francisco Lopez de Villalobos and Juan de Vigo, are not even mentioned by this author. The former wrote an authoritative treatise in 1498 entitled *Las bubas*, the latter a treatise in 1517 entitled *La mal français*.

Without presuming to impeach the reviewer's impressions, the only inference I can make from this quotation is that Dr. Butler is not familiar with these authors and that these works support the myth of the American origin.

Being grateful to Dr. Butler for a photostat copy of the whole poem in its original text, *Del licenciado de Villalobos, sobre las contagiosas y malditas bubas: estoria y medicina*, printed at Salamanca by Antonio de Barreda in 1498 (the copy in the British Museum), I feel it my duty to absolve him of any charge of ignorance of this work.

If the reviewer means by the work of Juan de Vigo which he calls *La mal français* his fifth book, entitled *De Morbo Gallico*, first published at Rome in 1514, then I would say that the works of neither of these authors makes mention or hints at an American origin for syphilis. And I can testify from personal knowledge that Dr. Butler is familiar with both of these works. More than thirty years ago I met Dr. Butler in the West Indies and accompanied him to leper hospitals and to other hospitals out of pure professional interest in disease and sickness among peoples of primitive habits. His experience as director of public health of the Haitian Republic was no casual contact with the diseases of which he is endeavoring to give his impressions.

In view of the liberal and tolerant expressions of the reviewer on the vexed question of the identity of yaws and syphilis, more than ever it would seem to me that we are approaching a time to overthrow an exotic traditionalism, with a view of examining the past in the light of its more reasonable biologic and social aspects.

Agreeing with the reviewer, I admit that to the ordinary physician the object of Captain Butler's book is of little interest as yet. That new National Social Hygiene Day is not until Feb. 3, 1937. I believe that to the layman the question is confusing, and also to the physician, particularly one who

reads current accounts of the work of Juan de Vigo, to learn that the disease appeared at Rome in December 1494 in epidemic form with the arrival of Charles VIII on his way to Naples; and then going into the subject one learns that the French army arrived at Rome Dec. 31, 1494. But little attention is given to the history of disease, not I believe because the ordinary physician is incapable of being interested but because he does not have the time to go deeply into these subjects. At the Atlantic City session of the American Medical Association in 1935, a part of a day in the Section on Miscellaneous Topics was given to the History of Medicine, because our Canadian brethren jointly meeting with us had such a section. At this time a resolution was offered that the American Medical Association organize such a section, but it died in stillbirth. When there is more encouragement in the field of medical history the ordinary physician will grow more interested, and the layman will be less confused.

Until the obstacle of the American origin of syphilis is attacked and if possible removed, no investigation into the far reaching biologic and social aspects of the antiquity of the disease we now call syphilis will be possible.

R. C. HOLCOMB, M.D., Upper Darby, Pa.

Captain, Medical Corps, U. S. Navy, retired.

*To the Editor:*—In connection with the review of my book "Syphilis Sive Morbus Humanus" (*THE JOURNAL*, Dec. 5, 1936, p. 1915): If it is of no interest to the general practitioner that two conditions such as yaws and syphilis are proved identical, if it would be of no interest to the profession of the United States and the world to expunge from our textbooks the monstrosity called yaws, then I am no judge of what is important and what is not. Yet your reviewer admits that the points here are proved and patronizingly commends my "zeal."

The American Medical Association should be interested in getting the truth about this important subject to the 100,000 or so physicians of the United States and Canada instead of expecting one physician to bear the whole load, as I have done for many years.

The Association's stand as regards the second item of my purpose in writing this book, viz., to expose the fallacy of the American origin of syphilis, is also discreditable. In the Commemoration Volume of 1915 the Association permits Dr. William Allen Pusey to commit the physicians of America to this American origin affair—the thesis of a discredited German, whose writings were not allowed to pass through the mails in Germany before his death. If there is one thing my book does show up it is the fallacious stand of these would-be American history interpreters. The thing is preposterous and certainly not to the credit of American medicine that one man can continue to teach the laity and the medical students of the United States this perfectly patent fallacy.

Now as regards the first item in which your reviewer finds that I have signally failed! If you look up the references in my book you will find that on the 19th of February 1934 the writer of "Syphilis Sive Morbus Humanus" was the first person, medical or lay, to advocate and insist on the use of the medical names of the venereal diseases by the newspapers and in radio broadcasting. This address, delivered in February 1934, was published in the *Medical Record* 140:592-594 (Dec. 5) 1934. Since that time the name "syphilis," which previously never occurred in the newspapers and was tabu by all the radio companies, is being used by both in all the large cities of the United States. Well the record speaks for itself. If you would do me the justice, not to say the courtesy, to publish this in your correspondence, I would appreciate it.

C. S. BUTLER, M.D.,

Naval Medical Center,

Washington, D. C.

which the breast was removed and may cause much distress. Also, nursing from only one breast subjects the patient to breast irritation at too frequent intervals. Therefore it is usually advisable to avoid breast feeding if the mother has only one breast.

Pneumonia or any other serious acute infectious disease is a contraindication to nursing. The mother rarely has milk in such cases, she should not be subjected to the strain and discomfort of nursing, and the risk is too great of transmitting infection to the baby.

#### DANGER IN ERGOT PREPARATIONS FOR HEADACHE

To the Editor:—A woman, aged 51, has had frequent and intractable headache for about fifteen years. The onset followed a slight head injury in which she sustained a bump against the bow of an automobile top. At that time headache occurred at intervals of once or twice a month. For the past two years the attacks have been more frequent and last always two and sometimes as long as eight days. The headache is chiefly occipital and there has been no nausea or visual disturbance. There is no family history of migraine. She has a history of rheumatic fever at 16 and 19, two attacks of generalized aching said to have been muscular rheumatism, and an infected foot some years ago. The menopause occurred in 1932. There have been no symptoms referable to any other part of the body except pain and tenderness over the right sacro-iliac joint. The tonsils and teeth have been removed. General physical and neurologic examinations disclosed nothing to account for the headache. The patient had a well compensated mitral stenosis. Roentgenograms of the cervical spine were not abnormal, nor was the urine. The spinal fluid was not examined. All previous medication had given no relief. She was given a solution of ergonovine in teaspoonful doses as follows: March 3, one dose; March 16, two doses, at 6 and 8 a. m.; March 17, two doses, at 6 and 8 a. m.; March 23, two doses, at 6 and 8 a. m.; March 24, one dose; April 5, one dose; April 8, one dose; April 18, three doses, at 6, 8 and 10 a. m. On each occasion the headache has been relieved by from one to three doses and naturally the patient is very enthusiastic about the treatment. The two cases of gangrene following the hypodermic use of ergotamine tartrate reported in *THE JOURNAL* May 9, 1936, have raised the question in my mind as to whether there may be danger with this other ergot preparation in the dosage employed. I would appreciate any information covering this point. Please omit name.

M.D., Texas.

ANSWER.—There is certainly such danger. The remedy should be used as sparingly as possible and an effort made to find a suitable succedaneum. As the ergot derivative probably acts by modifying the circulation disturbance in the affected part, other agents affecting the circulation in a somewhat similar manner, e. g., epinephrine or ephedrine, may be tried. The cerebrum exciting and insomnia inducing effect of the latter may be antagonized by combination with phenobarbital. Acetylsalicylic acid probably owes part of its action to redistribution of blood, so that a large dose of it, from 0.6 to 1 Gm., is well worth trying in a case of this kind.

#### BLOOD-TINGED SEMEN

To the Editor:—Kindly advise me as to the possible etiology, treatment and results of cases similar to this: A well developed man, aged 45, a Negro, occupied professionally and living in a good environment, came to my office several months ago with the complaint of blood mixed with semen on ejaculation following coitus. Such a condition has existed for about a year and varies from a trace to an amount sufficient to cause alarm. There is no pain accompanying ejaculation. A thorough physical examination revealed two abscessed teeth (right upper molars), which have been removed, a hypertension with the systolic pressure reading 204 mm. and the diastolic pressure 130 mm., which has been appreciably reduced, and a moderately enlarged prostate gland. The blood Wassermann test was negative, a complete blood count was normal and a urinalysis showed only a trace of albumin. I might add that the patient is apparently a highly nervous type and above the average intellectually. He states that coitus is not in excess and at times only once a month; also if he has a priapism without gratification and a small amount of secretion follows, no blood is evidenced nor is there any before, during or after micturition or any interference of it. He further states that he has not had any gonorrheal infection nor does any evidence show at present. It is apparent that the blood-tinged semen occurs only at the termination of coitus and he is now reluctant to indulge for fear of some serious development. Kindly outline the proper procedure or any information that will aid me in clearing up such a case and, if you please, omit name and address.

M.D., Oklahoma.

ANSWER.—The appearance of blood-tinged semen at the end of coitus is almost always due to a pathologic condition in the prostatic urethra. If the blood came from the seminal vesicles, the entire semen would be uniformly bloody. It is therefore essential to introduce a cysto-urethroscope and carefully look over the entire prostatic urethra without the introduction of any local anesthetic. Often this reveals a polyp or other tumor or an erosion or even an intense congestion of all the parts. The treatment consists in removing whatever pathologic condition is found. The prognosis is excellent.

#### PAROSMIA AND VISUAL DISTURBANCES

To the Editor:—A man, aged 42, a printer, suffers from a large choroidal lesion of the right macular field. The vision is reduced to 20/70 and there is a central scotoma for form and color. Previous to impairment of vision he smelled an odor of rotten onions, which during the past six or seven weeks to an odor of "burnt eggs." The odor is annoying and is disturbing his appetite. The general physical condition is good. The sinuses (roentgenologically and clinically) are normal. A neurologic examination was essentially negative, except for diminution of smell on the right side. Tests for lead poisoning were negative. The Mantoux reaction was positive and he is receiving cutaneous injections of new tuberculin T. R. I will appreciate your advice as to diagnosis and further procedure; also as how to relieve the annoying odor.

M.D., New York.

ANSWER.—This patient is suffering from parosmia in addition to a visual disturbance. Two conditions are suggested by the history. The first is that of an inflammatory lesion (arachnoiditis) at the base of the right frontal lobe. The second condition is that of a neoplasm at the base of the brain in the right frontal region involving the right olfactory bulb and nerve as well as the right optic nerve. Usually the parosmic sensations disappear after a period and anosmia results. This is especially true if there is a tumor and no attempt is made to remove or decompress it. It is suggested that the patient's smell be tested for response to coffee and citral. The test and interpretation of these tests can be found in an article by Elsberg in the April 1936 issue of the *Bulletin of the Neurological Institute of New York*. A careful search should be made for a primary malignant neoplasm of the bronchus, parotid and stomach. Saturnism usually does not produce a syndrome as described. Tumors of the uncinate gyrus of the temporal lobe produce so-called uncinate fits, which are characterized by abnormal sensations of smell in association with a convulsive state. Here lateralizing signs are found on neurologic examination. An exploration of the right anterior fossa is indicated if there is further progress of loss of visual acuity, field defects and loss in sensation of smell.

#### USE OF YEAST NUCLEIC ACID IN ALLERGY

To the Editor:—In the August 1935 issue of the *Archives of Otolaryngology* Dr. Ruskin of New York wrote an article about the use of nucleic acid in nasal conditions and I cannot find just what this is or just how it is given (dispensed) and more details about its use. He makes it sound quite good and as I am looking for new and better ways I wish to get some and try it in my work. I cannot even find who makes it and so am coming to you with my request for information. One man I asked said it was yeast and another said it is made from yeast. If this is answered in *THE JOURNAL*, please omit name and city.

M.D., Alabama.

ANSWER.—The nucleic acid referred to is yeast nucleic acid, sold by Merck or Fleischmann. It is administered either in powder form of 10 or 15 grains (0.65 or 1 Gm.) three times a day or in capsules, two or three 5 grain (0.3 Gm.) capsules three times a day.

Nucleic acid represents nonprotein nitrogen and it seems that the feeding of nonprotein nitrogen is of value in allergic cases. It has also been useful in severe eczema.

In seasonal hay fever the discomfort is considerably diminished and in some cases entirely relieved if the patient takes the nucleic acid beginning about one month prior to the usual onset of symptoms and continued throughout the period of irritation.

#### OPERATIONS FOR IMPOTENCE

To the Editor:—Please advise me whether ligation of the dorsal vein of the penis is really effective when there is too rapid emptying of the vein, and what ill results may follow such procedure. I am unable to get much from the literature at my disposal on this matter. Please omit name.

M.D., Arizona.

ANSWER.—Lydston in the *American Journal of Clinical Medicine* (1903) published an article recommending ligation of the dorsal vein of the penis for the relief of impotence. The effects he noted were twofold, mechanical and psychic. However, the results were not long lasting and the procedure was given up.

Lowsley reports excellent results with both animals and man by tightening the ischiocavernosus muscle on each side and the bulbocavernosus muscle by means of ribbon-gut. Because the gut does not tear through the delicate muscular structures, a large percentage of the patients on whom he has operated, the total now being fifty-one, have been relieved by this operation. He has modified by tightening the two leaves of the suspensory ligament, thus compressing the dorsal vein of the penis but not tying it off altogether. He secures best results in cases of impotence due to traumatism (rupture of the urethra) and

ticularly in the presence of high temperatures. The initial inflammation of the respiratory tract with propriety may be associated with the cause mentioned, provided, in fact, the paper involved was of the sulfite variety. On the other hand, the persistent manifestation in one patient scarcely may be attributed to the direct action of these vapors. The initial chemical irritation probably has been followed by an ordinary sinusitis, in which infection plays a part and which, at the present time, is none other than the highly prevalent sinus disease.

#### DANGERS OF GOMCO INTRA-UTERINE SILVER RING

To the Editor:—Will you please publish the following inquiry, omitting name? Please advise if the gomco intra-uterine silver ring is a safe contraceptive measure. If possible, please advise, first, if it is a safe procedure to leave the intra-uterine silver ring in for a year or more at a time, of course, using strict antiseptic measures in introducing it. Is it considered an efficient contraceptive method? M.D., Georgia.

ANSWER.—All intra-uterine devices are a source of danger to a woman even though they are introduced under strict antiseptic conditions into a uterus believed to be free from infection at the time. Should the woman have any type of infection, serious complications may be expected. The silver ring referred to does not prevent conception but usually makes nidation impossible. The American Medical Association Committee on Contraceptive Practices has gathered the following data from recent literature:

Many recent reports have emphasized the dangers associated with intra-uterine contraceptive devices. Not only are these appliances so inefficient that many pregnancies have been reported during their use, but they are dangerous in that severe and sometimes fatal pelvic infection follows their employment. There is also a growing conviction in Europe that their use increases the incidence of tubal pregnancy.

Recently the German medical profession has become so convinced of the harmful effect of these appliances that it has requested the appropriate governmental department to prohibit their manufacture and sale (Berlin letter, *THE JOURNAL*, Aug. 24, 1935, p. 611).

Gesenius (Berlin letter just cited) reports that several pregnancies have been observed in the Second Berlin Frauenklinik. Gummert (quoted by Warner, M. P.: Dangers of Gold Stem pessaries, with Reports of Three Cases, *M. Rec.* 142:69 [July 17] 1935) reported ninety-two pregnancies in women wearing stem pessaries, with seventy-eight abortions, 80 per cent of which were septic. Thirty-seven patients had peritonitis, seven had perforations of the uterus, and ten died.

J. H. Leunbach (Gräfenberg "Silver Ring" and Inter- and Intra-Uterine Pessaries, *J. State Med.* 40:37 [Jan.] 1932) reports four pregnancies while Gräfenberg rings were in situ and records the following results from these silver rings in the 174 other patients of his series:

- 55 rings removed:
  - 2 to increase family.
  - 3 for gonorrhea.
- 50 for bleeding, pain, tenderness and discharge.
  - 2 patients had serious fever and acute pelvic inflammatory disease.
- 35 rings spontaneously expelled.
- 55 rings in place and no complaints worth mention (roentgen examination).
- 15 rings presumably in place (no roentgen examination).
- 7 patients with pain, bleeding and discharge (rings will have to be removed).
- 6 patients not traced.
- 1 patient pregnant in tube when ring was inserted.

174 total (45 per cent comfortable).

Vignes and Boros (Lésions consécutives à l'emploi des pessaires anticonceptionnels intra-utérins, *Gynécologie et obstétrique* 29:244 [March] 1934) quote Rust as having reported 367 cases of serious pelvic disease following the use of intra-uterine contraceptive devices and list these sequelae as follows:

- Death from generalized peritonitis or septicemia, 17 cases.
- Purulent infection of the adnexa or parametritis, 70 cases.
- Generalized peritonitis, 38 cases.
- Pelvic peritonitis, 6 cases.
- Septic abortion, the pregnancy and abortion having occurred during the time that the pessary was in place, 62 cases.
- Perforation of the uterus by the pessary, 5 cases.
- Perforation of the bladder wall, 1 case.
- Perforation into the anterior culdesac, 1 case.
- Endometritis with fever, 75 cases.
- Menorrhagia, 60 cases.
- Dysmenorrhea, 28 cases.
- Ectopic pregnancy, conception having occurred while the pessary was in situ, 4 cases.

H. O. Jones (The Cervical Pessary, a Menace to Health and Life, *THE JOURNAL*, May 14, 1932, p. 1738) has recorded more than a dozen cases of severe pelvic peritonitis and parametritis, including one case in which death from endocarditis occurred four months after insertion of the pessary. Keller (Les dangers des pessaires intra-utérins, *Gynécologie et obstétrique* 32:417 [Aug.] 1933) has seen two patients with bilateral pyosalpinx and three others with pelvic peritonitis, one of whom developed secondary generalized peritonitis and died. Gesenius (*Zentralbl. f. Gynäk.* 59:2168 [Sept. 14] 1935) collected the following data during a survey of the literature:

	Severe Damage	Deaths
Stem pessary .....	346	38
Silk pessary .....	21	2
Ring pessary .....	78	1

Glaser (Die Gefahr intrauteriner Fremdkörper, *Deutsche med. Wchschr.* 59:994 [June 30] 1933) records thirteen serious pelvic infections with one death. Approximately one half of these patients had infiltrating and exudative parametritis, while the remainder developed adnexal tumors and severe peritonitis. In every instance, prolonged treatment was required.

Many other reports are available emphasizing the dangers inherent in these devices, and the committee feels justified in indicating its complete disapproval of these methods of contraception, which are still unfortunately widely employed by the medical profession. Every one who has done much obstetric or gynecologic practice has seen patients illustrating the bad effects of these devices and their inefficiency as contraceptives.

#### SPASM OF MASSETER MUSCLE

To the Editor:—A patient is suffering from a localized tetany of the left masseter muscle. This condition has been present for a period of about two years. She is about 30 years of age, is married, and is the mother of one child. In her past history there is only one significant finding: because of a hyperthyroid condition she had a subtotal thyroidectomy about six years ago. Extensive search for any foci of infection has failed. Urinalysis is negative and the blood Wassermann reaction is negative. This condition first started with occasional spasms of the left masseter muscle and gradually became of such intensity that she chipped off portions of her back molar teeth on that side during some of these tetanic contractions. Cold, emotional excitement and especially the chewing of food seem to be the chief things that bring on the attacks. Assuming that this was probably due to a hypoparathyroid condition, I placed her on 100 units of parathyroid extract three times a week, with 60 grains (4 Gm.) of calcium gluconate and 40 grains (2.6 Gm.) of ammonium chloride one-half hour before meals three times a day. After about six weeks of this treatment I could see no improvement, and I placed her on moderate doses of chloral hydrate with potassium iodide (empirically) three times a day. This has alleviated the condition considerably. Would it be feasible to do an injection treatment of the masseter branch of the trigeminal nerve at the site at which it crosses the mandibular notch of the mandible? If it would be feasible to do this, what would be the best solution to use and how long would one expect to get results? Would there be any resulting after-effects that would nullify the good results? Please omit name. M.D., West Virginia.

ANSWER.—Since all the conservative treatments used in an attempt to relieve the spasm of the left masseter muscle adequately have failed, some operative procedure to relieve the spasm seems indicated. The most satisfactory result would be obtained from paralyzing the masseter branch of the trigeminal nerve. Since this would be a very difficult procedure by either the closed or the open alcohol injection method, a simpler method would be to inject the third division of the trigeminal nerve at the foramen ovale with procaine hydrochloride. If this relieves the spasm completely for the period of resulting anesthesia in the left lower lip and corresponding half of the tongue, the alcohol injection could be done, since the motor branch of the fifth nerve is always paralyzed in a complete injection of the third division of the trigeminal nerve. The motor paralysis following alcohol injection of the third division usually lasts from six months to one year. It is true that the patient will be subjected to a complete anesthesia of the left lower lip as well as the left half of the tongue, but there will be no interference with the ability to masticate her food properly on the right side. One way to be certain that the motor root has been paralyzed is to have the patient open her mouth. When she attempts to do this the jaw will deviate to the left.

A more permanent procedure would be to do an intracranial section of the motor root. This, however does not seem to be indicated in this particular patient. The technic of alcohol injection of the divisions of the trigeminal nerve is given in detail in *Surgery, Gynecology and Obstetrics* 61:394 (Sept.) 1935.

by Flagg (Philadelphia, J. B. Lippincott Company, 1932) and the book "Anesthesia" by Gwathmey (New York, Macmillan Company, 1924) are both valuable and practical books on general inhalation anesthesia. The best information on the technic of general anesthesia is given by Guedel in a series of articles entitled "Anesthesia: A Teaching Outline" (*Cur. Res. Anesth. & Analg.* 15:1 [Jan.-Feb.], 55 [March-April], 120 [May-June] 1936). These articles should appear in book form in about a year. There are textbooks on anesthesia in the process of preparation now that are intended to be of practical value and should be available in from eighteen months to two years. For one greatly interested in the subject of anesthesia, Harris's translation of Braun is to be recommended.

#### EFFECTS OF LONG CONTINUED USE OF EPHEDRINE

*To the Editor*—I happen to be one of the unfortunates who have hay fever and who cannot seem to get any value out of pollen extract injections, but I am fortunate enough to be able to take ephedrine in sufficient dosage to obtain complete relief without getting any of the ill effects from the drug. For three years prior to last year I used ephedrine with almost ideal results and took three-fourths grain (0.05 Gm.) three times daily without any nervous effects, and the only thing unpleasant was a slight constipation, which was easily handled. Then I was warned by some fellow physicians that I might get the same effect from that drug which the old sufferers from chronic asthma get from the long use of epinephrine; namely, arteriosclerosis. Naturally I had no desire to have anything like that and stopped the use of ephedrine except for an occasional dose to precede an operation or delivery. Please give me an opinion as to the dangers of the drug. I realize that I would be using it for only about five weeks. I might also state that it does not seem to raise my blood pressure any, and my normal pressure is never over 110 systolic and is usually lower, which is low for age 38. M.D., Kansas.

**ANSWER.**—Ephedrine does not have the great blood pressure raising tendency of epinephrine and it has never been shown to produce arteriosclerosis in man.

#### MORPHINE IN CONVULSIONS OF CHILDHOOD

*To the Editor*—Is morphine contraindicated in the treatment of convulsions in children? Can death be attributed to morphine when it is used in the treatment of convulsions or when used in the control of severe attacks of bronchial asthma?

Rocco J. Martoccio, M.D., Utica, N. Y.

**ANSWER.**—In view of the fact that the reflexes and spinal functions are stimulated by morphine, it is generally avoided in the treatment of convulsive seizures. It may nevertheless be a useful adjunct to other treatment when status epilepticus or violent chorea or convulsions of intracranial origin threaten life by interfering with sleep. In such conditions, infants from 6 to 12 months of age may be given 1 mg. by hypodermic injection. It is of course possible by excessive dosage of morphine to produce death. Recent studies seem to indicate that its toxicity is not unproportionately greater for infants than for adults, as was formerly believed to be the case.

#### USE OF FACE MASKS IN PREVENTION OF INFLUENZA

*To the Editor*—As you probably know, the habit is widespread in Japan of wearing a mask over the nose in days when there is an epidemic of influenza, on the theory that doing so cuts down the incidence of the disease. Is there any reliable evidence one way or the other on this point? Do the Japanese health statistics show any lower level of respiratory diseases than our own, for example?

Bruce Bliven, New York.

**ANSWER.**—There is no reliable evidence at hand with respect to the effect of face masks on the incidence of influenza. It is altogether doubtful whether there are any comparable statistics that would give a reliable answer to the second question.

#### ROENTGEN ALOPECIA

*To the Editor*—My brother, now 27, was treated for ringworm of the scalp when he was 13, by means of x-rays. He has been partially bald since. He is in good physical condition. What is the prognosis in this case and what would you advise in the way of treatment? Please omit name.

M.D., Saskatchewan.

**ANSWER.**—Roentgen alopecia is permanent and is not amenable to treatment of any kind. The prognosis as far as restoration of the hair is concerned is hopeless and no treatment can be advised. It is questionable whether ringworm of the scalp should be treated with x-rays at the age of 13, as the disease clears up spontaneously at the time of puberty.

#### DEFINITION OF ACHLORHYDRIA IN ANEMIAS

*To the Editor*—Please clarify for me the terms "achlorhydria," "achylia gastrica" and "absence of free hydrochloric acid," particularly with reference to pernicious anemia. In spite of a clear definition, I have found them used interchangeably in the literature. Is there an absolute rule referable to the observation of gastric analysis in this disease? Please omit name.

M.D., Maryland.

**ANSWER.**—Although the terms "achlorhydria," "absence of free hydrochloric acid" and "achylia gastrica" are frequently used interchangeably in the literature, when used correctly the two former terms are synonymous and should be used to indicate an absence of free hydrochloric acid. The term "achylia gastrica" means an absence of all the normal gastric secretions, including hydrochloric acid, rennin and pepsin and perhaps even the intrinsic factor described by Castle. This condition is occasionally but not always found to be present in pernicious anemia. Unless tests are made which will rule out the presence of these various stomach secretions and if only the finding of an absence of free hydrochloric acid is demonstrated by the customary fractional test meal, the condition should be referred to as "absence of free hydrochloric acid" or "achlorhydria."

#### ANTISYPHILITIC TREATMENT IN RHEUMATIC HEART DISEASE

*To the Editor*—What would be the plan of antisyphilitic treatment for a woman, aged 28, with a rheumatic heart and a 4+ Wassermann reaction? The duration of the condition is unknown. The heart is more of the class B or C type. Please omit name. Thank you.

M.D., New York.

**ANSWER.**—Intravenous arsenicals are not advisable in such a case. The likelihood of doing good by their use is not great enough to compensate for the slight risk involved. It is better to give a saturated solution of potassium iodide, from 10 to 15 drops three times a day, and an intramuscular injection of mercury or bismuth compounds: mercuric succinimide, from 0.013 to 0.026 Gm. (one-fifth to two-fifths grain) twice a week for ten doses, to be followed possibly by sodium bismuth tartrate, 2 cc. (1.5 per cent solution) twice a day. The antisyphilitic treatment in the presence of rheumatic heart disease is on the whole not encouraging and should not be pushed if it seems to make matters worse.

#### BITTERLING TEST FOR ESTROGENIC SUBSTANCE

*To the Editor*—In Queries and Minor Notes in *THE JOURNAL*, Aug. 5, 1936, page 449, it was stated that the bitterling test has been found valuable in diagnosing ectopic pregnancy, missed abortion and placental polyp in the theory that these fish react to excess of estrogenic substance. Kleiner, Weisman and Barowsky (*THE JOURNAL*, April 13, 1935, p. 1318) showed that the test was not a test for pregnancy but that normal male and female urines might produce positive reactions. Kleiner, Weisman and Mishkind (*THE JOURNAL*, May 9, 1936, p. 1643) demonstrated that the test was really a test for male hormone and not for female hormone. Recently we have proved this point by getting reactions with minute doses of synthetic crystalline androsterone and testosterone. All these facts are reviewed and amplified in our latest publication (*Zoologica* 21: 241 [part 4] 1936).

I. S. KLEINER, PH.D.  
A. I. WEISMAN, M.D.  
D. I. MISHKIND, B.S.  
New York.

#### GASTRORRHAGIA

*To the Editor*—In reading your answer to the query regarding gastrorrhagia (*THE JOURNAL*, Dec. 19, 1936, p. 2072) I was interested to see your recommendation of the use of moccasin venom. This calls to mind a case of epistaxis the cause or location of which could never be determined. Blood examinations were repeatedly negative, except for an increasing secondary anemia. No evidence of a blood dyscrasia could at any time be determined. All forms of therapy, including transfusion, were of no avail. After nineteen days with daily attacks of epistaxis the bleeding practically stopped on the first injection of 0.4 cc. of moccasin venom and completely stopped the second day on 1 cc. of the venom. In four months there has been no recurrence. I trust that you will be interested in this, as the case was apparently one of idiopathic bleeding which moccasin venom undoubtedly stopped.

WILLIAM SULLIVAN, M.D., Alhambra, Calif.

*To the Editor*—On page 2072 of *THE JOURNAL*, Dec. 19, 1936, a condition is described of which I myself have been a victim. I reported my own case at some length in the *American Journal of Dermatology, Cases and Nutrition* 3:69 [March] 1936. A partial gastrectomy done under the impression that the basic lesion was a bleeding duodenal ulcer appears to have been effective, as I have had no further hematemesis over three and a half years. The tissue removed at operation was reported entirely negative by a competent pathologist.

C. D. ENFIELD, M.D., Los Angeles, Calif.

ticularly in the presence of high temperatures. The initial inflammation of the respiratory tract with propriety may be associated with the cause mentioned, provided, in fact, the paper involved was of the sulfite variety. On the other hand, the persistent manifestation in one patient scarcely may be attributed to the direct action of these vapors. The initial chemical irritation probably has been followed by an ordinary sinusitis, in which infection plays a part and which, at the present time, is none other than the highly prevalent sinus disease.

#### DANGERS OF GOMCO INTRA-UTERINE SILVER RING

To the Editor:—Will you please publish the following inquiry, omitting name? Please advise if the gomco intra-uterine silver ring is a safe contraceptive measure. If possible, please advise, first, if it is a safe procedure to leave the intra-uterine silver ring in for a year or more at a time, of course, using strict antiseptic measures in introducing it. Is it considered an efficient contraceptive method? M.D., Georgia.

ANSWER.—All intra-uterine devices are a source of danger to a woman even though they are introduced under strict antiseptic conditions into a uterus believed to be free from infection at the time. Should the woman have any type of infection, serious complications may be expected. The silver ring referred to does not prevent conception but usually makes nidation impossible. The American Medical Association Committee on Contraceptive Practices has gathered the following data from recent literature:

Many recent reports have emphasized the dangers associated with intra-uterine contraceptive devices. Not only are these appliances so inefficient that many pregnancies have been reported during their use, but they are dangerous in that severe and sometimes fatal pelvic infection follows their employment. There is also a growing conviction in Europe that their use increases the incidence of tubal pregnancy.

Recently the German medical profession has become so convinced of the harmful effect of these appliances that it has requested the appropriate governmental department to prohibit their manufacture and sale (Berlin letter, *THE JOURNAL*, Aug. 24, 1935, p. 611).

Gesenius (Berlin letter just cited) reports that several pregnancies have been observed in the Second Berlin Frauenklinik. Gummert (quoted by Warner, M. P.: Dangers of Gold Stem pessaries, with Reports of Three Cases, *M. Rec.* 142:69 [July 17] 1935) reported ninety-two pregnancies in women wearing stem pessaries, with seventy-eight abortions, 80 per cent of which were septic. Thirty-seven patients had peritonitis, seven had perforations of the uterus, and ten died.

J. H. Leunbach (Gräfenberg "Silver Ring" and Inter- and Intra-Uterine Pessaries, *J. State Med.* 40:37 [Jan.] 1932) reports four pregnancies while Gräfenberg rings were in situ and records the following results from these silver rings in the 174 other patients of his series:

- 55 rings removed:
    - 2 to increase family.
    - 3 for gonorrhea.
  - 50 for bleeding, pain, tenderness and discharge.
    - 2 patients had serious fever and acute pelvic inflammatory disease.
  - 35 rings spontaneously expelled.
  - 55 rings in place and no complaints worth mention (roentgen examination).
  - 15 rings presumably in place (no roentgen examination).
  - 7 patients with pain, bleeding and discharge (rings will have to be removed).
  - 6 patients not traced.
  - 1 patient pregnant in tube when ring was inserted.
- 174 total (45 per cent comfortable).

Vignes and Boros (Lésions consécutives à l'emploi des pessaires anticonceptionnels intra-utérins, *Gynécologie et obstétrique* 29:244 [March] 1934) quote Rust as having reported 367 cases of serious pelvic disease following the use of intra-uterine contraceptive devices and list these sequelae as follows:

- Death from generalized peritonitis or septicemia, 17 cases.
- Purulent infection of the adnexa or parametritis, 70 cases.
- Generalized peritonitis, 38 cases.
- Pelvic peritonitis, 6 cases.
- Septic abortion, the pregnancy and abortion having occurred during the time that the pessary was in place, 62 cases.
- Perforation of the uterus by the pessary, 5 cases.
- Perforation of the bladder wall, 1 case.
- Perforation into the anterior culdesac, 1 case.
- Endometritis with fever, 75 cases.
- Menorrhagia, 60 cases.
- Dysmenorrhea, 28 cases.
- Ectopic pregnancy, conception having occurred while the pessary was in situ, 4 cases.

H. O. Jones (The Cervical Pessary, a Menace to Health and Life, *THE JOURNAL*, May 14, 1932, p. 1738) has recorded more than a dozen cases of severe pelvic peritonitis and parametritis, including one case in which death from endocarditis occurred four months after insertion of the pessary. Keller (Les dangers des pessaires intra-utérins, *Gynécologie et obstétrique* 32:417 [Aug.] 1933) has seen two patients with bilateral pyosalpinx and three others with pelvic peritonitis, one of whom developed secondary generalized peritonitis and died. Gesenius (*Zentralbl. f. Gynäk.* 59:2168 [Sept. 14] 1935) collected the following data during a survey of the literature:

	Severe Damage	Deaths
Stem pessary .....	346	38
Silk pessary .....	21	2
Ring pessary .....	78	1

Glaser (Die Gefahr intrauteriner Fremdkörper, *Deutsche med. Wchschr.* 59:994 [June 30] 1933) records thirteen serious pelvic infections with one death. Approximately one half of these patients had infiltrating and exudative parametritis, while the remainder developed adnexal tumors and severe peritonitis. In every instance, prolonged treatment was required.

Many other reports are available emphasizing the dangers inherent in these devices, and the committee feels justified in indicating its complete disapproval of these methods of contraception, which are still unfortunately widely employed by the medical profession. Every one who has done much obstetric or gynecologic practice has seen patients illustrating the bad effects of these devices and their inefficiency as contraceptives.

#### SPASM OF MASSETER MUSCLE

To the Editor:—A patient is suffering from a localized tetany of the left masseter muscle. This condition has been present for a period of about two years. She is about 30 years of age, is married, and is the mother of one child. In her past history there is only one significant finding: because of a hyperthyroid condition she had a subtotal thyroidectomy about six years ago. Extensive search for any foci of infection has failed. Urinalysis is negative and the blood Wassermann reaction is negative. This condition first started with occasional spasms of the left masseter muscle and gradually became of such intensity that she chipped off portions of her back molar teeth on that side during some of these tetanic contractions. Cold, emotional excitement and especially the chewing of food seem to be the chief things that bring on the attacks. Assuming that this was probably due to a hypoparathyroid condition, I placed her on 100 units of parathyroid extract three times a week, with 60 grains (4 Gm.) of calcium gluconate and 40 grains (2.6 Gm.) of ammonium chloride one-half hour before meals three times a day. After about six weeks of this treatment I could see no improvement, and I placed her on moderate doses of chloral hydrate with potassium iodide (empirically) three times a day. This has alleviated the condition considerably. Would it be feasible to do an injection treatment of the masseter branch of the trigeminal nerve at the site at which it crosses the mandibular notch of the mandible? If it would be feasible to do this, what would be the best solution to use and how long would one expect to get results? Would there be any resulting after-effects that would nullify the good results? Please omit name. M.D., West Virginia.

ANSWER.—Since all the conservative treatments used in an attempt to relieve the spasm of the left masseter muscle adequately have failed, some operative procedure to relieve the spasm seems indicated. The most satisfactory result would be obtained from paralyzing the masseter branch of the trigeminal nerve. Since this would be a very difficult procedure by either the closed or the open alcohol injection method, a simpler method would be to inject the third division of the trigeminal nerve at the foramen ovale with procaine hydrochloride. If this relieves the spasm completely for the period of resulting anesthesia in the left lower lip and corresponding half of the tongue, the alcohol injection could be done, since the motor branch of the fifth nerve is always paralyzed in a complete injection of the third division of the trigeminal nerve. The motor paralysis following alcohol injection of the third division usually lasts from six months to one year. It is true that the patient will be subjected to a complete anesthesia of the left lower lip as well as the left half of the tongue, but there will be no interference with the ability to masticate her food properly on the right side. One way to be certain that the motor root has been paralyzed is to have the patient open her mouth. When she attempts to do this the jaw will deviate to the left.

A more permanent procedure would be to do an intracranial section of the motor root. This, however does not seem to be indicated in this particular patient. The technic of alcohol injection of the divisions of the trigeminal nerve is given in detail in *Surgery, Gynecology and Obstetrics* 61:394 (Sept.) 1935.

## Book Notices

**Urology.** By Edward L. Keyes, Ph.D., F.A.C.S., F.R.C.S., Professor of Urology, Cornell University Medical College, New York, and Russell S. Ferguson, A.B., M.D., Assistant Professor of Urology, Cornell University Medical College, New York. Sixth edition. Cloth. Price, \$10. Pp. 707, with 360 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1936.

This edition carries on the tradition of the Keyes urology—an admirably written example of dogmatism. The volume is divided into eleven sections, which cover the field of urology. Urology has become such a broad subject, however, that one man's experience is insufficient to cover the field, and certainly there are sections of this textbook of urology which are very weak. One wonders just what place this will fill in the physician's library. Certainly it is too sketchy to serve as a reference book for the urologist. As a volume destined for the general practitioner, it falls down in that one of the poorest sections is that on the treatment of urinary infection. On the other hand there is too much detail, especially as concerns malignant disease, to recommend the volume for the medical student. The technic of irradiation is not complete enough to interest the radiologist. It would seem from the criticism that the book fails to serve any useful function. Such is not the case, however, as it is a most interesting volume and undoubtedly gives a sound basis for urologic practice if one realizes that certain recommended procedures are debatable; e.g., the Ombrédanne operation as the procedure of choice in hypospadias. This operation, the only one described, must certainly be followed by stricture and hair in a large proportion of cases.

Any dogmatic work is open to criticism in that when one does not agree with the statement made there is no way to check the process of reasoning by which the authors arrived at the dogma. When the authors discuss the indications for nephropexy, it is not clear what relation the  $pH$  of the urine plays. The statement is made that, if the  $pH$  is not low, nephropexy and denervation should be performed. Can one then assume that, no matter what the degree of ptosis and hydronephrosis, one should not fix the kidney if the  $pH$  is low? Transurethral prostatic resection is "an utterly unsurgical procedure . . . that provides miserable, inadequate drainage for blood clots through the urethra." One stage suprapubic prostatectomy with closure, however, the bladder being drained with a 24 F. catheter, is a recommended procedure. Needle biopsy is a safe procedure for high grade kidney neoplasms and metastatic lung tumors but is justified in testicular tumors only if immediately followed by a full erythema dose of high voltage x-rays if the biopsy should be positive.

Previous editions of this book have given references when names are mentioned. This desirable feature has been omitted, and even initials in certain common names are missing. This is bound to be confusing if one attempts to follow a subject further, especially when errors have crept in. For example, a Thompson ureteral stone extractor is described. This does not exist. The unqualified recommendation for the use of anterior pituitary-like substance in the treatment of undescended testicles is unjustified. Certainly with our present knowledge this principle must be used with caution. It can be concluded that this is a valuable book for the practicing urologist, as it is both interesting and instructive to have a man's opinion of urology after forty years' experience in its practice. That one may consider an opinion narrow on certain subjects and open to criticism does not detract from its value in the least.

**Die Krankheiten der Nieren und ableitenden Harnwege.** Von Prof. Dr. Hans Lucke. Aus der medizinischen Klinik Göttingen (Direktor: Prof. Dr. H. Strubel). Brauns. Price, 2.50 marks. Pp. 83. Leipzig: Georg Thieme, 1936.

Dr. Lucke states, in a short introduction, that this small book was published at the suggestion of the editor of the *Deutsche medizinische Wochenschrift*, in which his work first appeared. It was presented primarily for the benefit of the general practitioner as a short review. He divides the work into two parts: The bilateral hematuric renal diseases (medial kidneys) and the so-called surgical diseases of the kidneys. It is a comprehensive but short review, well done, and eliminates all unnecessary and irrelevant matters. First

he discusses the normal kidney, then the symptoms and signs of renal disease, especially the pathologic urinary excretions, hypertension, function and edema. Uremia, anuria, the nephroses, nephrosclerosis and congested kidney are described. Surgical disorders of the kidney are nicely and shortly presented, especially tumors, tuberculosis, calculus and infections. The monographic review can be recommended to student and practitioner alike, and the trained urologist as well may find it useful.

**Nostrums and Quackery and Pseudo-Medicine. Volume III.** By A. J. Cramp, M.D. With a foreword by George H. Simmons, M.D. Cloth. Price, \$1.50. Pp. 232, with illustrations. Chicago: American Medical Association, 1936.

In 1911 the first volume of *Nostrums and Quackery* came from the presses of the American Medical Association. Ten years later—in 1921—enough material had accumulated to make another book, and volume II was brought out. By 1930 more than enough material had again accumulated to make a third volume, but unfortunately the economic situation at that time made it impractical to bring out volume III. It was not until recently that it was feasible to prepare the third volume of *Nostrums and Quackery*.

Volume III differs fundamentally from the previous volumes in that it is mainly a factual record. The material that makes up this book is a condensation by the author of longer and more detailed articles that he prepared between 1921 and 1935 and published in *THE JOURNAL*, in *Hygia*, and in the many pamphlets issued by the Bureau of Investigation.

The chapters that go to make up the book run the gamut of quackery from asthma and hay fever remedies to venereal remedies and include sections on cosmetics, food fads and nutrition nonsense. If you want to know what is in that widely advertised "diabetes cure," "obesity nostrum" or "stomach remedy," you will find chapters on such subjects. Here are exposures of "magic horse collars," electric belts and blankets, and a "tank treatment," "height-increasing" frauds, mail-order spectacle quackery, and numerous "rejuvenators," glandular and otherwise.

Here also are descriptions of fake liquor habit "cures," goiter necklaces, "electric shoe-plates" and preposterous "nose shapers"; the "Neurocalometer" of the chiropractic gentry, and the "electronic reactions" of Albert Abrams; William Howard Hay's "Sun-Diet" and Percy Lemon Clark's "Sanatology"; reproduced testimonials for various "cures" and the writers' death notices; the "cancer cures" of Baker, Hoxsey, Koch and others; "beauty clays" and "hair growers," the "Spectro-Chrome Therapy" and a variety of miscellaneous fakes.

Those interested in therapeutic vagaries will find in the new *Nostrums and Quackery and Pseudo-Medicine* an invaluable reference to what's going on in the "twilight" world of medical hokum.

**Synthetische geneeskunde: Een nieuwe ziektelezer en ziektebehandeling.** Door J. L. C. Wortman, Oud-geneesheer-directeur. Paper. Price, 3.25 florins. Pp. 224. Haarlem: de Erven F. Bohn N. V., 1936.

Realizing with many other writers that medicine stands at the crossroads, the author propounds a new theory of disease and a new treatment of the patient, which aim at putting medicine on a higher level by delivering it from the clutches of analysis. He thinks that, although physicians have not yet advanced far enough to construct a synthetic medicine in all its subdivisions, for which analysis may for a time be allowed to continue furnishing the scientific foundations, it seems that it is high time that they remember the teachings of Hippocrates and discard the nosologic system, with its fiction of diseases divorced from patients, which is useless in practice. They should concern themselves with constitutions and raciality, study the laws of heredity. The unity of the living body and the interdependence of its organs, maintained by the circulation and the nervous system, lead unavoidably to a synthetic theory of disease and treatment. The individuality of the patient must lead to a new anatomy, which will take into account the physiologic deviations of the various individuals, while a new clinical physiology will study the functional differences between different patients, their compensatory functions and compensatory treatment. Protein shock and other means for combating hyperemia will claim attention, and vaccination prophylaxis

ciently severe cerebral trauma may be responsible for aggravating the potential convulsive state; likewise a chronic infection at the base of the brain may influence cerebral circulation adversely and aggravate the potential convulsant type.

The treatment suggested in view of the long intervals between convulsive seizures should include routine standardization of fluid intake, diet, exercises, rest, and regulation of the bowels. The fixation of weight at a definite level is the best criterion for avoidance of cyclic states of hydration and dehydration leading to abnormal disturbance of water balance.

#### ITCHING IN HODGKIN'S DISEASE

*To the Editor:*—Please give me information on the treatment of itching and of cough in Hodgkin's disease. You may omit name.

M.D., Massachusetts.

**ANSWER.**—The treatment of pruritus and of cough in Hodgkin's disease is symptomatic if the patient has received adequate therapy with radium or x-rays.

There is no consistent relationship of the pruritus and the course of the disease. In some cases it may precede any of the characteristic symptoms and disappear as the disease progresses, while in others it appears late or persists throughout the entire clinical course. When the pruritus is associated with a true infiltration of the characteristic granulation tissue in the skin, it not infrequently responds to x-rays. For symptomatic relief of intractable pruritus, drugs that lessen the sensibility of the cutaneous nerves are often used. Phenol, menthol and camphor are either incorporated in calamine lotion or are prescribed in ointment form and applied to the parts that are affected.

The following prescriptions or their modifications are suggested:

	Gm. or Cc.
R Phenol .....	0/5
Menthol .....	1/0
Calamine lotion .....	180/0
	Gm. or Cc.
R Menthol .....	0/5
Camphor .....	1/0
Oil of sweet almond .....	2/0
Hydrous wool fat .....	25/0

Calcium chloride given intravenously has been successfully used by some men to allay persistent pruritus in Hodgkin's disease.

The cough may be a pressure symptom or actual involvement of the lung by the characteristic granulation tissue. In the former case the symptom usually abates with roentgen or radium therapy over the mediastinum, while in the latter case it is a persistent symptom and can be controlled only by drugs that depress the cough reflex.

#### EFFECTS OF NOISES ON ORGANS OF CORTI

*To the Editor:*—I should like to know what damage, if any, and the nature and location of the pathologic condition that might result to the ear while one is using a telephone and experiencing a sudden, sharp pistol-like report or noise, which the patient described as having shocked or stunned her and was followed immediately by subjective noises and an impairment of hearing in the ear. I have a patient who had such an experience in what she claimed was a perfectly normal ear. I saw her the next day and there was decreased bone conduction; she was unable to hear a watch on contact and heard a spoken voice at 10 feet and a loud whisper at 18 inches. There was no electrical storm present when this happened. I am anxious to know whether it is possible for the ear to be damaged by such an experience while using a telephone and, if so, the seat and nature of the pathologic change and the prognosis.

MEADE EDMUNDS, M.D., Petersburg, Va.

**ANSWER.**—When there is any lesion of the ear caused by loud noises, pistol shots, and so on, it is usually the organ of Corti that shows changes. A severe concussion may cause rupture of the drum membrane. In experimental animals subjected to one or two or sometimes many loud noises close to the head, histologic examination later has shown degeneration in certain portions of the organ of Corti, depending on the pitch of the noise used. In the case under discussion, it is quite likely that there is a lesion in the inner ear as shown by the decreased bone conduction and the marked change in hearing acuity. There has been a great deal of interest in this subject but practically nothing in the literature. The only reference we have been able to find is that of an article by A. Moriez (Auditory and Neurologic Disturbances Caused by Traumatizing Telephone Noises, *Rev. d'oto-neuro-ophth.* 2:171 [March] 1933). A case is cited of a man, aged 65, in whom there was considerable involvement of the perception apparatus due to noises in the telephone receiver. Telephone engineers state that ear symptoms cannot be due to any electrical shocks from the tele-

phone or the telephone lines themselves. If there is any difficulty it must arise from the noises in the telephone and not from the electric current. It is strange in view of the widespread use of telephones that the literature does not contain more citations of cases.

#### SYPHILIS OF SPINE

*To the Editor:*—A white man, aged 45, had generalized weakness and loss of weight. His past history was negative, as was his family history. There were no symptoms referable to any particular system of the body except for weakness and the loss of 40 pounds (18 Kg.) in the last nine months. The physical examination shows him to be fairly well nourished, with an extreme degree of jaundice, which he says is of three weeks' duration and has caused no pain. Examination reveals a rather marked kyphosis of the lumbar dorsal spine, of which the patient was unaware. There have been no digestive disturbances. The knee kicks were present and active. The pupils were normal. The examination of the urine was negative. The examination of the blood showed the Kahn reaction to be positive 4. Blood examination revealed hemoglobin 85 per cent, erythrocytes 4,840,000, color index 0.8 and leukocytes 8,500, with a differential count of polymorphonuclears, 68 per cent, lymphocytes 31 per cent and eosinophils 1 per cent. The serum bilirubin is 38 mg. per hundred cubic centimeters, with a direct Van den Bergh reaction. The x-ray examination of the spine shows what appears to the roentgenologist to be an old arthritic process with extensive fusion of the vertebrae. However, there is superimposed on this an acute disintegrative process with destruction of the bodies of the first and second lumbar vertebrae, including the intervertebral disks. The roentgenologist suspects Charcot spine. I am perplexed as to what course to pursue in the matter of treatment. Would the administration of arsenicals be likely to result in toxic hepatitis in view of the jaundice? Is intensive antisyphilitic therapy indicated? Is a laparotomy indicated? Should one suspect a malignant condition of the pancreas or of the gallbladder? Should the entire picture be attributed to syphilis? Ought I to be content to treat the man with large doses of iodides and a bismuth compound? Please advise me. Thus far he has had no antisyphilitic therapy.

M.D., New Jersey.

**ANSWER.**—The entire picture might be due to syphilis and could be treated by antisyphilitic measures. There is a possibility of a metastatic malignant condition. The most likely diagnosis is syphilis of the spine; that is, Charcot's spine, or gumma of the vertebrae. The patient may have a pancreatitis or hepatitis. The spine might be treated locally by means of a curved Whitman, Bradford or Herzmark frame, to be followed by a plaster cast and later a spine brace. A fusion operation might be considered.

From the general standpoint, it might be beneficial to prescribe aminoacetic acid and a high caloric diet.

#### DILATION AND CURETTAGE OF UTERUS—INDICATIONS FOR WEANING

*To the Editor:*—1. How soon after a pelvic operation, especially one such as dilation and curettage, should a woman be allowed to have intercourse with her husband? 2. How long is a woman kept in bed after a dilation and curettage? I understand there has been a change in the after-treatment. 3. After an instrumental delivery is it customary to keep the baby from nursing, feeding it artificially for two or three days? I have been told that this is the practice in some hospitals because of the fear of convulsions. Or is such practice limited to those suffering with mouth injuries from the forceps? 4. What diseases necessitate the cessation of nursing a baby, that is, diseases of the mother? Would an attack of pneumonia justify one in removing the baby and giving it artificial feeding?

E. L. DAVIS, M.D., Kijabe, East Africa.

**ANSWER.**—1. Sexual intercourse may be indulged in as soon as pelvic discomfort and inflammation subside, ordinarily after about one week.

2. The length of time a patient should be kept in bed after dilation and curettage varies greatly with the pathologic condition encountered. In a simple case two or three days should suffice.

3. It is excellent practice to give artificial feeding to all newborn babies, tiding them over the period during which there is no milk. After cesarean section or other serious surgical intervention, the mother rarely recovers sufficiently to nurse the baby during the first two or three days.

It is unnecessary to keep an instrumentally delivered baby from nursing because of the fear that it will develop convulsions. Babies injured by forceps develop convulsions despite nourishment, not because of it.

4. A tuberculous mother, or one suspected of having tuberculosis, should not nurse her baby.

A history of multiple breast abscesses after a previous childbirth is usually a contraindication to nursing. Badly inverted tender nipples often make nursing inadvisable. If a breast has been amputated, nursing from the other breast often stimulates residual islands of mammary gland tissue on the side from

rheal and rheumatic disorders. The generalized conclusions are drawn out to four pages and are repeated in Danish. A complete bibliography is one of the best parts of the entire endeavor.

**A Medical History of Sullivan County, Indiana.** By James B. Maple, M.D. Cloth. Pp. 153, with illustrations. Sullivan, Indiana: The Author, 1936.

A signal service has been performed by Dr. Maple to Sullivan County in collecting and putting into permanent form such a fund of local historical information. To perform his task has required an immense amount of work, which can be repaid only by the appreciation of those who at present and in the future value such unselfish service. The text is filled with interesting anecdotes about the men described. It is to be hoped that what Dr. Maple has written may stimulate interest in the erection of a suitable monument in Johnson Cemetery at the grave of Jane Todd Crawford, the celebrated patient on who Ephraim McDowell performed his first operation for the removal of an ovarian tumor.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Accident Insurance: Death from Acute Alcoholism.**—The plaintiff was the beneficiary named in two life insurance policies issued to his wife by the defendant insurance companies. Each policy contained a clause obligating the insurer to pay double indemnity in event the insured should die "through external, violent and accidental means." The insured died of acute alcoholism after consuming an unknown quantity of a beverage consisting of alcohol and ginger ale. The insurance companies paid the face amounts due under the policies but declined to pay under the double indemnity clauses. The plaintiff thereupon sued the insurance companies. The trial court transferred to the Supreme Court of New Hampshire, without a ruling, the question of the defendants' rights to a non-suit.

At the outset, said the Supreme Court of New Hampshire, it should be noted that what the insured did she did knowingly, voluntarily and without error or mistake on her part. She drank what she intended to drink in the quantity intended, and the beverage did not, unknown to her, contain any poisonous substance. What was unforeseen, unexpected and sudden was the effect of that beverage on her. She died an accidental death but it does not necessarily follow that she can be said to have died "through external, violent and accidental means." Some courts regard the words "accidental means" and the word "accidental" as synonymous. Other courts, while recognizing that their meaning is not the same, regard that distinction as either technical and inconsequential or else as an unwise one to draw. The weight of authority is that there is a substantial difference in the meaning of the words. The Supreme Court of New Hampshire was of the opinion that the majority rule is supported by the better reason. To give the same effect, the court said, to the phrase "accidental means" as to the word "accidental" is to ignore the presence of the word "means." Words are to be ignored or regarded as surplusage only when to do otherwise would be either to render the meaning unintelligible or else to produce a result obviously at variance with a clear intention or purpose. In the present case, effect may readily be given to the word "means," and the court could perceive no reason for not giving it effect. Although the word "accidental" standing alone may refer to either cause or result, the use of the word "means" in connection with it limits its meaning to cause alone.

It follows, concluded the court, that death supervening as an unforeseen, unexpected and unusual result of acts done knowingly, voluntarily and without error of mistake as to external agencies is not a death "through external, violent and accidental means." Judgments of non-suits were therefore entered for the defendants—*McKinley v. John Hancock Mut. Life Ins. Co.; Same v. Metropolitan Life Ins. Co. (N. H.), 144 A. 593.*

**Malpractice: Negligence of Hospital Not Provable by Lay Testimony.**—The plaintiff, a child, was severely injured in an automobile accident and was brought to the defendant hospital, a corporation, for treatment. Subsequently he sued the corporation, contending that his injuries were dilatorily diagnosed and negligently treated. The jury returned a verdict for the plaintiff, which the trial court set aside. The plaintiff thereupon sought a reversal in the Supreme Court of Appeals of West Virginia of the action by the trial court.

An instruction requested by the plaintiff submitted the alleged negligence of the defendant to the jury without defining what constituted negligence in medical and surgical treatment. While this instruction was incomplete, the Supreme Court said, the error was cured by another instruction given on behalf of the defendant which correctly informed the jury concerning the degree of skill and care required of a physician and which instructed the jury that the negligence of a physician in diagnosis or treatment may be established only by proof by other physicians.

There was lay testimony that the defendant hospital corporation permitted ants to get in a suppurating sore on the plaintiff. There was no evidence, however, that the plaintiff's condition was aggravated by the ants. The incident might indicate negligence, in the opinion of the court, but whether it was negligence resulting in harm to the plaintiff required specific evidence, and there was none. Likewise, the fact that witnesses for the plaintiff observed dirt on the plaintiff's wounds did not of itself raise a presumption of actionable negligent treatment. A physician who apparently had been in charge of the plaintiff at the defendant hospital testified, without contradiction, that on the plaintiff's admission a roentgenogram was made of "the pelvis, both hip joints and the right thigh." He further testified that he noted some symptoms of arthritis later on and that "about December 4th tenderness, redness and swelling of the left hip joint was discovered." After outlining the treatment given to the plaintiff for this condition, the witness explained his failure to take a roentgenogram during that period, by saying:

He (plaintiff) had an arthritis of almost every joint of his body . . . These were sore, tender and extremely painful. . . . He was highly nervous, I would frequently give him a sedative an hour before I would undertake to dress him because of his nervousness. . . . He was just beginning to improve a little bit . . . if I had taken him to the x-ray room I could be doing him no good. It would have been only to satisfy my curiosity, which did not seem enough reason to punish the patient.

If this testimony, said the court, did not answer the plaintiff's contention with respect to dilatory diagnosis, it certainly placed the question "beyond the ken of laymen."

The court disavowed any intention of holding that no actionable negligence existed in the present case. We simply hold, the court said, that, because of the plaintiff's extraordinary injuries with their subsequent complications, negligence in treatment must be fixed by some one competent to speak instead of by conjectures by laymen. Since there was in this case no such competent evidence, the judgment of the circuit court for the defendant was affirmed.—*Frazier v. Grace Hospital, Inc. (W. Va.), 185 S. E. 415.*

## Society Proceedings

### COMING MEETINGS

- American Association of Anatomists, Toronto, Ont., March 25-27. Dr. George W. Corner, 260 Crittenden Blvd., Rochester, N. Y., Secretary.
- American Association of Pathologists and Bacteriologists, Chicago, March 25-26. Dr. Howard T. Karsner, 2935 Adelbert Road, Cleveland, Secretary.
- American Heart Association, New York, Feb. 1. Dr. H. M. Marston, Jr., West 50th St., New York, Executive Secretary.
- American Orthopsychiatric Association, New York, Feb. 1-2. Dr. George S. Stevenson, 50 West 50th St., New York, Secretary.
- Annual Congress on Medical Education, Medical Literature and Hospitals, Chicago, Feb. 15-16. Dr. William D. Cutter, 535 North Dearborn St., Chicago, Secretary.
- Mid-South Post-Graduate Assembly, Memphis, Tenn., Feb. 16-17. Dr. A. F. Cooper, Goodwyn Institute Building, Memphis, Tenn., Secretary.
- Pacific Coast Surgical Association, Seattle, Wash., and American J. Co. Feb. 24-27. Dr. H. Glenn Bell, University of California Medical School, Francisco, Secretary.
- Southeastern Surgical Congress, Louisville, Ky., March 7-11. Dr. Benjamin T. Beasley, 472 Peachtree St. N.E., Atlanta, Ga., Secretary.

impotence in young men resulting from excessive sexual intercourse.

The operation is not suitable for older men because the condition of the muscles involved is usually not good.

#### TREATMENT OF URTICARIA

*To the Editor:*—I have a patient who is subject to an urticarial eruption on an average of about three or four times a week. I have been giving both local and symptomatic treatment, without success. The patient is getting calcium orally, ephedrine in a 1:1,000 injection and potassium citrate orally, including the treatment for digestive disorders. Because of a petit mal diagnosed by a previous physician the patient has been on phenobarbital therapy in the form of tablets. What relationship, if any, does the latter fact have (as a drug allergy) to the urticaria?

B. B. BACKLEY, M.D., Jacksonville, Ohio.

**ANSWER.**—Urticarial eruptions may be produced by drugs in the phenobarbital groups. It is essential in any scheme of treatment for the patient that this drug be interdicted. It is essential to determine whether the patient has a petit mal or a hystero-epilepsy. Urticarial eruptions of an obstinate type are often dependent on nervous or emotional factors. These factors must, of necessity, be controlled in order to obtain therapeutic success. All foci of infections, such as tonsils, gallbladder and prostate, and the ingestion of drugs in the coal tar or barbiturate groups should be ruled out.

The use of autohemotherapy by withdrawing 10 cc. of the patient's own blood and reinjecting it intramuscularly is used in the treatment of this condition. This may be given once or twice weekly. If there is no response, the antianaphylactic effect of peptone in 0.5 Gm. dose in capsules, twenty minutes before meals, should be considered. This may be combined with mercury with chalk, 0.065 or 0.13 Gm., after meals. Further therapy consists of limiting animal foods and giving *Bacillus acidophilus* by mouth.

#### COLITIS

*To the Editor:*—A woman, aged 29, who has had idiopathic ulcerative colitis for two years, at present has symptoms of nausea, soreness in the abdomen and more or less continuous diarrhea. She is taking a kaolin preparation and ferric ammonium citrate capsules. She seems to get a recurrence every winter and it was suggested that she go south each year. Would you suggest treatment with parathyroid, viosterol and calcium to be of much value in clearing up the symptoms? What else would you suggest in order to clear up these symptoms? Please send your answer as soon as possible. Please omit name. M.D., Conn.

**ANSWER.**—Chronic ulcerative colitis is a destructive infectious disease of the large intestine which should be considered much as we do tuberculosis. A well ordered program of management continued for many months is indicated. As relapses of this disease are prone to occur in association with infections of the upper respiratory tract, a warm equable climate without extreme changes in temperature seems to have a favorable effect in many cases. These patients should receive as much sunshine, fresh air and freedom from infections of the upper respiratory tract as it is possible to give them. In some instances this implies the use of artificial sunlight. Various iron preparations have been known to aggravate the diarrhea in these individuals. The medications suggested may be a factor in the patient's gastro-intestinal upset. An occasional patient has apparently received benefit from the administration of preparations of parathyroid and calcium.

#### VACCINATION AGAINST TETANUS IN THE FRENCH ARMY

*To the Editor:*—In a recent issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in the Foreign News you have a note concerning the use of vaccination against tetanus being made obligatory for every French soldier. Can you tell me where I can get more information on the type of vaccination used? Have there been any reports in French literature on the subject and are there any reprints available? I would greatly appreciate any material on the subject.

A. B. SCHWARTZ, M.D., Milwaukee.

**ANSWER.**—Since August 1936 every soldier in the French army has been obliged to be vaccinated against tetanus. Three subcutaneous injections each containing 2 cc. are given at intervals of fifteen days of a mixture containing the tetanus and diphtheria anatoxins (Ramon) as well as the antityphoid and paratyphoid vaccines. Up to December 1936, 400,000 soldiers had been given these mixed anatoxin and vaccine injections. A second injection of 2 cc. of the same mixture will be given one year later to all these soldiers. These associated vaccinations were fully discussed by Prof. G. Ramon in the first and second volume of the *Revue d'immunologie*.

#### PERSONALITY PROBLEM

*To the Editor:*—I am seeking information relative to constructive advice to be given to a young protégé of mine. The boy is 16 years of age and perfectly normal physically. He has a bright, retentive mind and is a talented guitarist. The family history is unimportant; he originates from plain, wholesome midwestern stock. The lad's difficulty seems to express itself in undue diffidence and lack of aggressiveness. He has numerous opportunities to play in semiamateur orchestras, but unless urged by an older sister to take advantage of them he seems quite indifferent and lackadaisical. I have just learned that between the ages of 5 and 7 he stammered noticeably and was found to be left handed. He since has developed ambidexterity but writes altogether with his left hand. I recall vaguely having read of this syndrome as being responsible for an inferiority complex in children. Please advise me of the titles of suitable books dealing with this situation. I should like to know of at least one book suitable for perusal by the boy himself.

M.D., Missouri.

**ANSWER.**—The personality disturbance in this patient may be related to certain early difficulties such as are indicated by the history of stammering and left-handedness. It is advised that he shall not be given books to read concerning inferiority complexes but that he see a psychiatrist who will go into the early development and life history of the patient and by a study of the individual himself attempt to find the etiologic factors in this personality difficulty. Generalizations do not help the individual case. For the inquirer's own reading "Psychopathology" by William Malamud is recommended.

#### VITAMINS AND STERILITY

*To the Editor:*—Please inform me as to the value of "wheat germ oil" in cases of sterility. The patient's husband has been examined, the cervix is patent, and several glandular extracts have been given. Kindly omit name.

M.D., Alabama.

**ANSWER.**—It is possible to diminish the breeding capacity of laboratory animals by subjecting them to various sorts of deficient diet. The absence of any vitamin will induce some diminution of fertility. On this basis one has come to recognize the value of so-called vitamin E, present in wheat germ oil.

An analysis of average mixed human diets, however, indicates that they contain an excess of all the essential vitamins over and above the basic requirements of the organism. It seems unlikely, therefore, that therapeutic administration of any principle of this sort will improve the fertility of the ordinary human being. Other lines of investigation and treatment are indicated.

#### ETIOLOGY OF THYMIC ENLARGEMENT

*To the Editor:*—A woman, aged 29, was extremely nervous and harassed by the husband during the term of pregnancy. She had a normal delivery. The child died twenty-three days later of an enlarged thymus. Would it be possible for the enlarged thymus to have been caused by the nervous and harassed condition of the mother? Kindly omit name.

M.D., Pennsylvania.

**ANSWER.**—While it is impossible to state with certainty that nervousness in the mother could not bring about an enlarged thymus in the child, this effect would seem altogether unlikely. It has been found that calves shipped with their mothers across the continent have small thymus glands. It would appear that in the trip the hardships endured in hunger, thirst and neglect result in poor nutrition in the young and atrophy of the thymus gland. In order to obtain the best extracts of the thymus gland, locally bred calves are used, animals that have been nursed by the cows in the morning and that have never been subject to hardships. Such animals usually present large, succulent glands. In addition, it should be stated that status thymicolymphaticus occurs in infants from time to time with no known cause. This is associated with large thymus glands, spells of dyspnea, stridor and cyanosis, and often ending in sudden death. So far as can be determined, nervousness in the mother is not a contributing factor to this clinical picture observed in infants. The cause of the enlarged gland in status thymicolymphaticus is still unknown.

#### BOOKS ON ANESTHESIA

*To the Editor:*—Which in your opinion is the most practical textbook on anesthesia?

Rocco J. Martocchio, M.D., Utica, N. Y.

**ANSWER.**—For regional anesthesia, Labat's "Regional Anesthesia: Its Technic and Clinical Application" (Philadelphia, W. B. Saunders Company, 1928) is probably among the most practical, and for local infiltration anesthesia, Hertzler's "The Technic of Local Anesthesia" (St. Louis, C. V. Mosby Company, 1933) is to be recommended. "The Art of Anesthesia"

per cent, the endothelial outnumbered the epithelial cells in only one instance, and the two types of cells were approximately equal in number in 15 per cent. It was concluded that a definite preponderance of endothelial over epithelial cells represents a glomerulitis. The highest incidence of glomerulitis was found in puerperal sepsis (52.4 per cent) and subacute bacterial endocarditis (78.9 per cent). The glomerulitis is probably due chiefly to endothelial proliferation, but the lodgment of mononuclear leukocytes in the capillaries seems to play a part of some importance. There is no anatomic basis for a diagnosis of focal glomerulonephritis except in instances of transitory glomerular bleeding not associated with symptoms of nephritis, and in cases of bacterial endocarditis.

**Lesions of Cardiac Valves in Rheumatic Fever.**—Gross and Friedberg studied the incidence and gross and microscopic appearance of lesions in the valves, valve pockets and chordae tendineae occurring in ninety-seven cases of rheumatic fever. Until comparatively recently the only gross rheumatic lesions known to occur in the heart were those due to the acute and healing stages of pericardial inflammation, the fresh and healed verrucae on the closure line and chordae tendineae insertions of the valves, the valvular deformities with the characteristic commissural agglutinations of the aortic cusps, the thickening of the chordae tendineae, the regurgitant endocardial pockets (also occurring in other conditions), the auricular endocardial lesions and, rarely, the macroscopic Aschoff bodies. To these there have been added recently the lesions at the roots of the great vessels which produce dimpling in the sinus pockets and the thickening and prominence of the subvalvular angles and ring regions. In the present study, descriptions are given of the more minute topographic changes found in the valves, including elongation of the auriculoventricular leaflets, with obliteration of their normal scalloping, the ham shaped chordae tendineae insertions, the approximation of the semilunar folds of the semilunar cusps to the free edges and their disappearance, the notching, entropion and ectropion of the semilunar cusps, the characteristic pocket lesions consisting of verrucous, polypoid and nodular formations, and the agglutinations and rounding of the auriculoventricular valve pockets with obliteration of their sharp angle. A description of the pathogenesis of these lesions, their life cycles and their incidence in the various clinical subdivisions of rheumatic fever is given.

**Respiratory Responses to Muscular Activity.**—Schneider and Crampton gave attention to the respiratory, metabolic and pulse rate responses to graded intensities of work on the bicycle ergometer, to work pushed to fatigue and to the recovery processes after strenuous effort in boys from 9 to 13 years of age. The boys usually reported for work immediately after the close of the afternoon session of school. After a rest for fifteen or twenty minutes the exercises were begun. A linear relationship between the consumption of oxygen and load of work was not in evidence. With light loads the intake of oxygen was too large and with heavy loads too small. The resting rate of consumption of oxygen increased with the growth of two boys and at the same time the delivery of

oxygen during strenuous work was augmented. During the minute volume, frequency and depth of breathing of preadolescent boys correspond to that of adults. The amount of air breathed per minute and the depth of breathing during exertion are smaller among boys than among adults, while the frequency of breathing is greater among boys. The respiratory dead space during physical exertion increases less in boys than in adults. The ventilation equivalent for oxygen is somewhat larger for boys than for men. During physical exertion the pulmonary alveolar oxygen pressure invariably rose. The oxygen debt was never large. After six months of growth the debt with a heavy load was reduced. Growth resulted in more favorable oxygen intake, in a larger lung ventilation, in a slower pulse rate and in a larger oxygen pulse, during both rest and exertion. In work carried to fatigue a steady state was ordinarily reached in all respiratory and metabolic factors; but the pulse rate, while maintaining a fairly steady state for a while, always showed some further accelerations with the onset of fatigue. In recovery the metabolism returned to the preexercise level before the pulse rate. Strenuous exertion more profoundly disturbs the circulation than the respiration and metabolism.

**Radiotherapy in Lesions About the Eye.**—Richards states that generally the eye tolerates radium rather well and with proper precautions it may be used safely in a variety of conditions. The dangers are corneal ulcer, secondary glaucoma and cataract. Granular lids or eczema along the edges of the lids usually responds well to unfiltered roentgen radiation. Papillomas may be destroyed by single pole fulcrum radiation followed by a light dose of radium. Simple rodent ulcer of the lid and remote from the lens or either canthus may be treated by a surface application of radium or by the implantation of highly filtered needles. The obvious dangers of treating the eye about the inner canthus are destruction of these structures, contracture and deformity of the lids, and interference with

# Medical Examinations and Licensure

## COMING EXAMINATIONS STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, January 23, page 324.

### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the country on April 17. *Oral examinations for Group A and B applicants* will be held in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held simultaneously in different centers of the United States and Canada in March. *Practical examination* will be given in St. Louis in April and at Philadelphia in June. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the United States and Canada, March 6. *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. *Applications must be received at least sixty days prior to the examination dates.* Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Philadelphia, June 12. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Chicago, March 26-27. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Michigan.

AMERICAN BOARD OF PEDIATRICS: Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 725 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF PSYCHIATRY & NEUROLOGY: Philadelphia, June. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Oral examination.* Minneapolis, June 25-26. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

## California Reciprocity and Endorsement Report

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports 31 physicians licensed by reciprocity and 3 physicians licensed by endorsement from Aug. 14 through Oct. 29, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of California Medical School.....	(1934)		New York
Georgetown University School of Medicine.....	(1925)		Kansas
College of Physicians and Surgeons of Chicago.....	(1906)		Illinois
Northwestern University Medical School.....	(1934)		N. Dakota
Rush Medical College.....	(1911), (1929)		Illinois
State University of Iowa College of Medicine.....	(1920), (1924), (1932), (1933)		Iowa
Tulane University of Louisiana School of Medicine.....	(1935)		Louisiana
Detroit College of Medicine and Surgery.....	(1922)		Michigan
University of Michigan Department of Medicine and Surgery			Oregon
University of ..			Michigan
University of ..			Minnesota
St. Louis Un ..			Missouri
Washington ..			New York
Creighton Un ..			Washington
University of ..			Nebraska,
(1927) Louisiana, (1932) Illinois			
University and Bellevue Hospital Medical College.....	(1919)		New York
University of Rochester School of Medicine.....	(1932)		New York
Ohio State University College of Medicine.....	(1935)		Ohio
University of Oregon Medical School.....	(1934), (1935, 2)		Oregon
University of Pennsylvania School of Medicine.....	(1920)		Utah
University of Tennessee College of Medicine.....	(1934)		Texas

## Georgia October Report

Mr. R. C. Coleman, joint-secretary, State Examining Boards, reports the written examination held by the Georgia State Board of Medical Examiners in Atlanta, Oct. 13-14, 1936. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. Three candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Emory University School of Medicine.....	(1933)		1
University of Georgia Medical Department.....	(1932)		1
Tulane University of Louisiana School of Medicine.....	(1935)		1

Six physicians were licensed by reciprocity and 2 physicians were licensed by endorsement on October 14 and December 2. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Chicago College of Medicine and Surgery.....	(1911)		Illinois
University of Illinois College of Medicine.....	(1933)		Illinois
University of Michigan Department of Medicine and Surgery		(1906)	S. Dakota
John A. Creighton Medical College.....	(1910)		Nebraska
University of Nashville Medical Department.....	(1910)		Arkansas
University of Virginia Department of Medicine.....	(1932)		Virginia

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Rush Medical College.....		(1917)	N. B. M. Ex.
Harvard University Medical School.....		(1933)	N. B. M. Ex.

## Minnesota October Report

Dr. Julian F. Du Bois, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held in Minneapolis, Oct. 20-22, 1936. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Forty-seven candidates were examined, all of whom passed. Six physicians were licensed by reciprocity and 4 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent.
Northwestern University Medical School.....	(1935)		89.3
90.2, (1936) 82.6, 86, 86, 88.3			
Rush Medical College.....	(1935)	86.3, (1936) 84.4,	90.6

Johns Hopkins University School of Medicine.....	(1912)		Maryland
Harvard University Medical School.....	(1905)		New Hamp.
University of Vermont College of Medicine.....	(1935)		Vermont

\* Verification of graduation in process.

tuberculosis was apparently converted into a fulminating tuberculous bronchopneumonia following such treatment. When dementia paralytica occurs in a tuberculous individual with an old healed lesion, it may have no effect on that lesion even though vigorous antisyphilitic treatment, including fever therapy, is given. Therefore diathermy and perhaps even malarial therapy may be attempted, but the patient should be watched even more closely than usual. Since patients with dementia paralytica live for considerable periods even in the presence of pulmonary tuberculosis, it would seem that, when the mental condition of the patient permits, the usual indication for such collapse therapy as pneumothorax and phrenico-exeresis might be employed with benefit.

"Alcohol" Amblyopia, Pellagra, Polyneuritis.—Carroll presents ten cases of the clinical syndrome variously called tobacco-alcohol, tobacco or alcohol amblyopia, which occurred in patients with the alcoholic type of pellagra or polyneuritis. Clinical entities such as pellagra and nutritional polyneuritis are relatively rare, but symptoms resulting from a deficiency in specific nutritional factors occur frequently. The alcoholic type of polyneuritis and the alcoholic type of pellagra are deficiency diseases associated with the lack of the vitamin B (B<sub>1</sub>, B<sub>2</sub>, and so on) fraction. The ten cases of "alcohol" amblyopia reported occurred in patients who had pellagra or polyneuritis or both. All these patients smoked in moderation, and all but one used only cigarettes. But they were all heavy drinkers: They consumed between 1 and 3 quarts of alcoholic liquor daily. Most of them were dipsomaniacs. In every case the diet had been inadequate.

### Colorado Medicine, Denver

33: 857-930 (Dec.) 1936

- Essentials of Adequate Testing of Hearing. A. E. Bowers, Denver.—p. 876.
- Nephropoiesis. J. C. Buntin, Cheyenne, Wyo.—p. 899.

**Surgical Shock from Burns and Freezing.**—According to Harkins, correlated laboratory experiments and clinical observations indicate that unrecognized blood loss is an important factor in traumatic shock. Shock in severe burns is usually associated with a leakage of blood plasma-like fluid into the burned tissues and from the weeping burned surface. Tannic acid may be of value in decreasing this loss. Experiments indicate that leakage of plasma-like fluid in amounts heretofore unrealized is present in other conditions, of which freezing is an example. In the treatment of freezing the effects of rapid thawing and low general body temperature are to be considered as well as plasma loss. Actinic, chemical, electrical and x-ray burns, because of the nature of their production, seldom cause a type of shock similar to thermal burns, although they could theoretically do so. The injury produced by these external agents may result in a general condition of shock as well as evident local trauma. Since the fluid lost in these conditions is plasma rather than whole blood, the ideal therapy might be

plasma infusion rather than whole blood transfusion. The author has used plasma experimentally but has not tried it clinically.

**Vertigo as Syndrome in Vascular Disease.**—Shapiro lists the following as vertigo arising from disturbances of the circulatory system: 1. Vasomotor instability without evidence of structural abnormality in the blood vessels forms a group comprising a large percentage of cases in which vertigo and other eighth nerve symptoms occur. There is no doubt that this is the basis of most of the so-called cases of the Ménière syndrome. Under the heading of vertigo due to vasomotor disturbances can probably be included the prodromal vertigo of epilepsy, a large percentage of the vertigo in chronic post-concussion states and certain cases of migraine that are accompanied by transient loss of half of the field of vision and violent vestibular upsets. 2. Any blood dyscrasias from simple anemia to the leukemias may cause vertigo owing to insufficient oxygenation of the vestibular structures. In addition, leukemic deposits and degenerative changes in the internal ear are responsible. 3. In circulatory disturbances with organic changes in the blood vessels of the internal ear or brain (including hypertension) the patients are particularly apt to complain of dizziness on stooping or arising quickly. The basic reason for the symptom lies in the inability of the sclerosed vessels to adjust themselves quickly to the effects of gravity, with resultant transient anemia. Abnormally low blood pressure is a far less frequent cause of vertigo than hypertension. 4. In cardiac abnormalities either an accelerated heart, such as occurs in paroxysmal tachycardia, or a retarded one in which the apex beats do not reach the periphery may be involved. An important group of symptoms is composed of vertigo or syncope attacks combined with extrasystoles that are evident only at the apex and a slow pulse; this is the well known Stokes-Adams syndrome due to partial heart block. In cardiac cases vertigo represents the mildest form of cerebral anemia due to deficient heart action; more pronounced cases lead to transient faintness, and still more severe involvement to attacks of complete unconsciousness with or without convulsive seizures.

### Indiana State Medical Assn. Journal, Indianapolis

20: 615-620 (Dec.) 1936

- Present Day Anesthesia. L. F. Sise, Boston.—p. 615.
- Diseases of Cervix Uteri. F. L. Adair, Chicago.—p. 621.
- \*Postoperative Thrombophlebitis. O. O. Alexander, Terre Haute.—p. 623.

- Psychiatry in General Practice. F. S. Caprio and G. H. Tamm, Marion.—p. 633.
- The Acute Mastoid. B. N. Lingeman, Crawfordsville.—p. 636.

**Postoperative Thrombophlebitis.**—Alexander believes that the use of preliminary barbiturates, opiates and spinal anesthetics is conducive to postoperative thrombus formation and that any procedure which can in any way lessen this hazard should be carried out with the greatest exactitude. A few

and blood purifying measures and nature cure methods must be rehabilitated. Synthetic thinking on the part of the physician will deliver medicine from the terrible oneness in which it has sunk during the last century as a result of purely analytic thinking and will establish it on a humanistic foundation, which will make it the leader of all sciences. The author cannot help admitting in various parts of his book that analysis has its good points, but he seems bent on not leaving any doubt that it had better be consigned to the limbo of forgotten things, that medicine would have fulfilled its object much better if it had adhered to the fundamental teachings of Hippocrates, and that physicians can do their full duty toward their patients only by following the precepts of nature cure medicine.

**Oral Hygiene and the Treatment of Parodontal Diseases.** By Russell W. Bunting, D.D.Sc., Professor of Oral Histology and Pathology in the School of Dentistry of the University of Michigan, Ann Arbor. Cloth. Price, \$2.50. Pp. 187, with 80 illustrations. Philadelphia: Lea & Febiger, 1936.

Eighty-five pages are devoted to oral hygiene, oral prophylaxis and instructions to patients. The remainder is concerned with the treatment of parodontal diseases, inclusive only of gingivitis, pyorrhea, Vincent's disease and gingival atrophy. The sections covering the last four conditions and prophylaxis are adequate and to be commended. In the first part the author digresses from his subject by discussing oral sepsis at some length, and of the chapter on pyorrhea about eight pages are of a historical character. No mention is made of the course outlines suggested by the Curriculum Survey Committee of the American Association of Dental Schools, and the text is characterized by its lack of conformity with the recommendations of this committee. These facts impose rather unelastic limits on its usefulness as a school textbook and as an inclusive guide for the practitioner. The statement on page 10 that "large and small areas of necrotic change were discovered in the bone and peridontal membrane about the apices of devitalized teeth" should be questioned. On page 96 the word "arterial" is used instead of bacterial. A critical examination of the contents discloses other minor defects of a similar character. There are two helpful bibliographies and a satisfactory index; the illustrations are excellent.

**La chirurgie du cancer du poulmon: Bases anatomo-cliniques et expérimentales. Technique opératoire.** Par O. Lambret, professeur de clinique chirurgicale, H. Malatray, chef de clinique chirurgicale, et J. Driessens, chef de laboratoire, à la Faculté de médecine de Lille. Paper. Pp. 198, with 17 illustrations. Paris: Masson & Cie, 1936.

This presents a good discussion of the subject of lung carcinoma. The first two chapters (thirty pages) deal with the diagnosis and pathologic anatomy. Then the surgical indications and experimental basis for surgery are described. There are fifty-six pages on the surgical technic, with excellent illustrations. In the sixth and seventh chapters the authors present a summary from the literature of forty cases of lung cancer treated with lobectomy and ten cases treated with pneumectomy. They present two cases of their own treated with removal of an entire lung. The book ends with a table of nineteen cases of lung carcinoma in which pneumectomy was done, and twenty pages of bibliography. The monograph is of value to surgeons engaged in thoracic surgery, which offers about the only hope of cure in early cases of lung cancer.

**Text-Book of Pathology.** By Sir Robert Muir, M.A., M.D., Sc.D., Professor of Pathology, University of Glasgow. Fourth edition. Cloth. Price, \$10. Pp. 994, with 571 illustrations. Baltimore: William Wood & Company, 1936.

This well known volume is intended primarily as a textbook for students of medicine; the subjects discussed have therefore been selected to present both the general scientific aspects of pathologic processes and those features of special pathology which are essential to the medical student in his approach to clinical medicine and surgery. About one fourth of the book deals with general pathology and the remainder with special subjects. The author in both sections makes an especial effort to correlate functional disturbances with structural changes. He is to be commended for having avoided the tendency of some authors to incorporate sections on bacteriology, parasitology and dermatology into textbooks of pathology; as a result, he has left the size of the book within convenient proportions.

The many illustrations are well selected and the index has been carefully prepared. Students of medicine will find this book a well balanced presentation of modern views of both general and special pathology.

**Snow on Cholera, Being a Reprint of Two Papers.** By John Snow, M.D. Together with a biographical memoir by B. W. Richardson, M.D., and an introduction by Wade Hampton Frost, M.D., Professor of Epidemiology, The Johns Hopkins School of Hygiene and Public Health. Cloth. Price, \$2.50. Pp. 191, with 3 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1936.

This book contains a reprint of two papers by John Snow, together with a biographic memoir by B. W. Richardson, M.D., and an introduction by Wade Hampton Frost, M.D., professor of epidemiology at the Johns Hopkins School of Hygiene and Public Health. Dr. Frost gives an interpretative introduction orienting the present-day reader with respect to the significance of Dr. Snow's contribution. Dr. Snow's two papers, on the Mode of Communication of Cholera and on Continuous Molecular Changes, more particularly in their relation to epidemic diseases, published in 1855 and 1853 respectively, are classics in epidemiology. His views on the mode of spread of cholera were confirmed in detail following the discovery of the specific cholera germ by Koch in 1883. The discussion of the chemistry of the blood of cholera patients and the effect of intravenous injections of saline solution in this disease, given on pages 11 to 13, are of modern interest. This book should prove a valuable asset to any library.

**Recollections of Richard Dewey, Pioneer in American Psychiatry: An Unfinished Autobiography.** Edited by Ethel L. Dewey. With an introduction by Clarence B. Farrar, M.D. Cloth. Price, \$2. Pp. 173, with illustrations. Chicago: University of Chicago Press, 1936.

These memories of a pioneer American psychiatrist were left incomplete by his death at the age of 85 and have been edited by his daughter. He describes his early life and his education just after the Civil War period. His experiences as a contract surgeon in the German army during the Franco-Prussian War are intensely interesting and alone justify acquiring the book. After his return to this country he engaged in the institutional care of the insane and was head of the State Hospital at Kankakee, Ill., from 1879 to 1893. Reforms he instituted there were widely adopted and revolutionized the care of the insane in this country. His memoirs constitute a valuable record of progress in this field.

**Leitfaden für den geburtshilflichen Operationskurs.** Von Dr. med. et Dr. art. obs. h. c. Albert Döderlein, Geheimer Rat, München. Sixteenth edition. Boards. Price, 4 marks. Pp. 245, with 175 illustrations. Leipzig: Georg Thieme, 1937.

The great popularity of this small book is attested by the fact that the present edition is the sixteenth since 1893. The book is divided into six parts. The first deals with the attitude and position of the fetus, the second is concerned with the mechanism of labor, the third takes up version and extraction, the fourth describes forceps operations, the fifth is a discussion of manual extraction of breech presentations and the sixth is devoted to destructive operations. There is an additional brief section on cesarean section and hysterectomy. One seventh of the book is devoted to destructive operations. This seems a disproportionately high allotment of space to this subject. Although the book was received for review in October 1936, the publishers have issued the book as having been copyrighted and printed in 1937. The book is clearly written and the illustrations are highly instructive.

**Clinical Studies of Endogenous Conjunctiva Affections.** By Carsten Edmund. Paper. Pp. 156. Copenhagen: NYT Nordisk Forlag: Arnold Busck, 1935.

This booklet consists of an analysis dealing with endogenous conjunctivitis, supplemented by individual cases seen in the hospitals of Copenhagen. The various forms of conjunctival troubles accompanying exudative erythema multiforme (Hebra), erythema nodosum, pemphigus, herpetiform dermatitis, and urticaria are described and compared as to the incidence and characteristics. Considerable stress is laid on the similarity between the fibromembranous forms of conjunctivitis that occur in stomatitis and in patients with phlyctenular keratoconjunctivitis that have been treated with sanocrysin. Finally are discussed the endogenous eye disturbances associated with gonorr-

harmlessness in therapeutic doses for the human system. Favorable results obtained in diabetic cases of lowering glycemia were most probably due to the activation of the glandular functions involving the production of more secretin and the stimulation of the glycogenic function of the liver, in addition to a possible "insulinoide" and the vitamins A and B. The preparation has successfully controlled 100 per cent of functional diabetes, returning blood sugar to normal or nearly normal on a liberal diet. In cases of atrophy and fibrosis of the pancreas, the true organic type, it has failed.

Joint Meeting of the Manila Medical Society and the Journal Club of the San Juan de Dios Hospital. J. C. Nanagas, Manila.—p. 625.

**Ide's Test for Syphilis.**—Quisumbing points out that the Ide test for syphilis can be applied (with slight variation in the procedure) to fresh or dried blood, to the spinal fluid and to the exudate obtained from the vesicles. In using fresh blood only a drop of blood, about 0.03 cc., is necessary. The blood, taken from the lobe of the ear or from the finger tip or from the vein, is placed on the concave surface of a hollow slide especially made for this purpose. A drop of 3.5 per cent saline solution is added and stirred with a corner of an ordinary object glass, and at the same time spread over the whole surface of the depression. Lastly, a drop of the Ide antigen is added. The whole mixture is shaken for three or four minutes by placing the hollow slide flat on a table and shaking forward, backward and sideways. The preparation is then ready for examination under a microscope. A positive reaction is shown by the appearance of purplish blue clumps among the red cells in the field, whereas if the reaction is negative no such change takes place and only the red corpuscles are seen. If the reaction is superpositive the purplish masses can be seen with the naked eye, but if it is weakly positive the aid of the microscope is needed. Of the 119 cases giving strongly positive Wassermann reactions, 116 gave a strong Ide reaction. Of seventeen cases giving weakly or doubtfully positive Wassermann reactions, six gave weakly or doubtfully positive Ide reactions and eleven cases failed to react. In 1,126 cases yielding negative Wassermann reactions, no positive Ide reactions were obtained.

**Urinary Alkalinity in Young Children.**—Neff and his associates state that dietary alkalinization of the urine, either alone or as an adjuvant to drugs, is feasible in acute pyelitis. Even young infants tolerate the amount of orange juice that is necessary to produce high alkalinity. An infant having acute pyuria uninfluenced by diet or drugs probably has an inaccessible and diffuse type of renal infection with sepsis. In chronic pyuria, alkalinity of the urine is the rule. Damaged renal function prevents the regulation of the acid-base equilibrium. Pyuria accompanying malformation of the urinary tract, renal calculus and infection with *Bacillus proteus* are known to be difficult to benefit permanently by diets or drugs. Acid-forming drugs or diet could not be used in one infant, but a great improvement occurred with dietary regulation and alkalinization. Experience with the feeding of five older children to whose diets base-forming juices were given showed that, with a general diet, from 8 to 16 ounces (240 to 480 cc.) of orange juice usually raises the  $pH$ . A high protein diet makes it difficult to render the urine alkaline by orange juice unless a pint or more is used, but the  $pH$  rose as high as 8.4 or more when grape juice was substituted for the orange juice.

**Syphilis as a Problem in Immunity.**—Chesney points out that the first and most important fact to understand about man's natural defensive reaction against syphilis is that it is far from being perfect. Although man's defensive reaction to syphilis is inferior to his reaction to most other infections, that reaction is by no means insignificant from the standpoint of protecting the individual. The syphilitic patient does acquire a measure of immunity or resistance against his infection. Patients who acquire syphilis and have none of the early clinical manifestations of the disease, and whose spinal fluids remain negative, likewise acquire an appreciable resistance against their infection. Such patients, who are discovered to have the disease only as a result of a routine Wassermann test, constitute a large proportion of our syphilitic population, and it may be asserted with assurance that they possess a relatively high degree of acquired resistance against the spirochete. The effectiveness of the resistance that is built up during the course of syphilis varies considerably in different individuals. The immune state engendered by syphilis is not imparted to all parts or tissues of the body alike. The precise details of the mechanism of the defensive reaction against syphilis are still unknown. Everything points against its being a humoral affair. The negative results from the study of blood and serum from syphilitic patients point to the tissues as being the seat of the immune mechanism. If human beings cannot acquire resistance

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Requests as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Hemophilia in the Negro.**—Crandall's review of the literature failed to reveal a case of undoubted hemophilia in the Negro. The case that he reports, excepting for the family history, is typical of hemophilia. In spite of frequent nosebleed in two brothers and a maternal uncle and grandfather, the family history cannot be interpreted as the genealogy of a hemophiliac patient. The patient is a very black Negro, without any ascertainable evidence of white ancestry, presenting a history of immoderate hemorrhages from several sources since early childhood. He further showed rapid recovery following hemorrhage and had also the characteristic mischievous temperament which Bulloch and Fildes noted as being so constant that it might be regarded as almost a minor feature of the disease. He developed hemarthrosis of the left knee and joint changes typical of those found in hemophiliac patients, though they are not pathognomonic. But one of the thirteen coagulation time tests was within normal limits. This one was taken during a period of active hemorrhage. The coagulation time was still markedly prolonged five months after cessation of hemorrhage. The platelet count, the tourniquet test, the clot retraction, and the Wassermann and Kahn tests were all negative. It is generally recognized that a qualitative defect of the blood platelets interfering with proper coagulation of the blood exists in hemophilia. Studies are being made calculated to prove or to disprove the existence of such a defect in the platelets of this patient.

**Hypoglycemia in Addison's Disease.**—Welty and Robertson cite two proved cases of Addison's disease that showed evidence of marked hypoglycemia with coma relieved by dex-

trose administration. In one case symptoms of the increased sugar tolerance overshadowed those of the destructive adrenal lesion and hindered the differential diagnosis. There was a relatively normal serum chloride level, which strengthens the belief that the dextrose was specific. Addison's disease should always be considered in the differential diagnosis when hypoglycemia is present. Hyperinsulinism and Simmonds' disease are perhaps the two disorders most difficult to rule out. The former can frequently be differentiated by the absence of the typical symptoms of pigmentation and hypotension. In addition, the dextrose tolerance curves of the two diseases differ rather characteristically. The six hour curve of typical hyperinsulinism tends to become progressively lower, and shock is usually observed before completion of the test; the curve of Addison's disease is relatively flat and does not decrease sharply, and shock is rare unless there are complicating factors, such as intercurrent infection or starvation, which may deplete the body dextrose supply. The dextrose tolerance curve of Simmonds' disease resembles somewhat that of Addison's disease. However, extreme cachexia, loss of sexual function and marked depression of the basal metabolic rate (with hypothermia and hypotension), together with loss of teeth and hair (axillary and pubic), are usually present, thus aiding in differentiation.

**Relation of Coronary Sclerosis to Symptoms.**—Polanco found that history of pain of cardiac origin was given in 14.9 per cent of the patients, 91.7 per cent of the instances being associated with marked sclerosis and 8.3 per cent with moderate sclerosis. No patients with mild sclerosis gave a history of pain. Dyspnea and cardiac pain were the symptoms encountered most frequently. Signs of congestive heart failure were also predominant; of the arrhythmias, auricular fibrillation was the most common and extrasystole was frequent. The anterior descending branch of the left coronary artery was the most frequent to be "markedly" involved in the sclerotic process (eighteen times). Of arteriosclerosis in other organs, the kidneys and spleen were more markedly attacked. Other organs were involved in varying degrees, showing that visceral arteriosclerosis tends to be generalized, although usually affecting the vessels of some organs more than others. The ratio of heart weight to body weight was found to be increased in 90.8 per cent of the 156 men and 91.3 per cent of the eighty-six women. The average heart weight in 149 men was 417 Gm., or 123 Gm. above normal. Of these, 84 per cent weighed more than normal. Of seventy-eight women the average weight was 387 Gm., or 137 Gm. above normal, 83.3 per cent showing definite increase of heart weight.

**Early Stages of Glomerulonephritis.**—Bell proposes the theory that subclinical glomerulitis differs from clinical glomerulonephritis only in intensity, making a broader approach to the etiology of glomerulonephritis available. A large group of infectious and toxic processes is concerned in the etiology of the disease. The glomerular capillaries are injured probably by various toxic substances. Sensitization to bacterial or other protein may play an important part, but it is unnecessary to assume that sensitization is essential in the development of the lesion. The cases of acute glomerulonephritis that develop within a week after the onset of an acute infection are not easily explained as a result of hypersensitiveness. A widespread sensitization to bacterial protein must be assumed if one is to explain subclinical glomerulitis on this basis. A microscopic study was made of the kidneys in 107 cases of death from accidental causes, 194 cases of death from noninfectious diseases and 564 cases of death from various infectious processes. In the 107 normal cases the glomerular epithelial cells definitely outnumbered the endothelial in 84.1

**The Human Body Louse in Transmission of Typhus.**—Covell and Mehta give an account of attempts to transmit the virus of a strain of typhus, originally derived from the brains of wild rats, from monkey to monkey by means of the human body louse. Out of sixty lice that were fed on experimentally infected monkeys, three (5 per cent) showed enormous numbers of bipolar staining Rickettsiae in smears from the middle intestine. Of three monkeys on which lice from the infected batch were allowed to feed, one developed a febrile reaction and another a slight rise in agglutinins for Proteus OX19. A fourth monkey, into the scarified skin of which lice which had died during the experiment were rubbed, developed a febrile reaction together with a slight rise in agglutinins for Proteus OX19. Guinea-pigs subpassaged from this animal have shown pyrexia for several generations, but no scrotal reaction.

**Facial Cellulitis.**—From their study of fifty-five cases of facial cellulitis, Chatterji and De find that Staphylococcus aureus constitutes the predominating organism among the bacterial agents. The common conception that this condition is due to Streptococcus haemolyticus is shown to be incorrect as far as Calcutta is concerned. In the pathogenesis of the disease an early onset of virulent septicemia dominates the picture, while spreading infective thrombophlebitis constitutes the most important pathologic process in the infected and surrounding area. Extension of infection into the cavernous sinus or the meninges is not so frequent. The majority of the patients die of septicemia before the infective thrombophlebitis has time to extend inside the skull. Clinically, the signs and symptoms exhibited are those of a fulminant septicemia with well marked toxemia. Pulmonary and cardiac involvements are always of serious significance. In the matter of treatment, a policy of nonintervention should be followed as a matter of choice. Except for minor details regarding the management of the local area, attention should be concentrated on the treatment of septicemia with its accompanying toxemia. There is great need for an effective specific antiserum for combating this infection. The mortality rate in the series of cases was 80 per cent. It is extremely doubtful whether this high death rate can be altered by any form of treatment that is available at present.

**Bismuth Compounds in Treatment of Endemic Syphilis.**—Hudson and Crosley treated 1,000 endemically syphilitic (bejel) seminomad Bedouins with bismuth compounds in the last four years. Bejel, the name by which endemic syphilis is locally known, affects 90 per cent of the village population in the region of Deir-ez-Zor. The first manifestation of the disease is a mucocutaneous eruption, which usually disappears spontaneously within a year and is followed by a latent period of some years. Late lesions take the form of mucocutaneous relapse or gummatous ulcerations. Periostitis and bone necrosis are found in both early and late lesions. Bejel does not attack the constitution or the vital structures of the body and is not transmitted congenitally. It is impossible to treat the bejel patient in a voluntary clinic along the lines of modern antisyphilitic therapy. In the case of an endemic syphilis such as bejel, the objective should be the eradication of the disease in the community. To gain this objective it is only necessary to control the infectiousness of the individuals with open lesions, and this can be secured with preparations of bismuth alone, at low cost, without risk to the patient, and in a time schedule adapted to the temperament of the Arab. In general, bismuth is most suitable for the capricious Bedouin patient, because if he abandons treatment early—as he often does—he has not been harmed, nor has the success of possible later treatment been prejudiced. Treatment consisted of daily intramuscular injections of bismuth in the form of sodium bismuth tartrate and bismuth salicylate. The subjects received an average total of 75 cg. of the metal in ten days. Improvement was usually immediate, and the healing effect was prolonged beyond the treatment period. Improvement was evident in 49 per cent of the patients, and 28 per cent were healed. The result of treatment was not known in 13 per cent, and 10 per cent were not changed. These results are satisfactory, considering that attendance at the clinic was entirely voluntary and treatment was paid for. The short intensive course of bismuth seldom reversed the positive Kahn reaction and often made it stronger. Occasionally, patients healed with bismuth had recurrences of bejel lesions. This not unexpected recurrence presented no difficulty, as healing was again secured with bismuth. Bismuth in the healing of open bejel lesions is as effective as the arsenicals and has two additional virtues—prolongation of effect and stimulation of the natural body defenses. Mass treatment, for which intramuscular injections of bismuth are suitable, should consist of the treatment of children to the age of 15 and of all adults with open lesions.

Anal Fissure. J. W. Riddoch.—p. 1159.

**New Method of Treatment in Hemophilia.**—In the course of investigations unconnected with hemophilia, Temperley and his associates found that if egg white was treated at 37 C. for several days in the presence of potassium bromide it was possible to extract from the mixture a substance the addition of which to blood in vitro under certain conditions led to the formation of a clear structureless red which did not shrink like the ordinary blood clot. This substance, when injected intravenously into cats (either decapitated or anesthetized),

the function of the lacrimal duct. In lesions near the outer canthus with slight or no ulceration the treatment is carried out by everting the lid, shielding the whole eye and the other tissues by a suitable lead shield and applying radium either as a surface application or by the insertion of highly filtered radium needles. The details of radium treatment are determined by the individual case but take the form of a surface application, a pack applied externally or the implantation of highly filtered radium needles. In hyperplasia of the corneal epithelium the eye is cocainized and the lids are retracted and held in position by retractors. A tracing of the hyperplastic tissue is taken on transparent celluloid and transferred to a piece of lead foil, and an opening is cut in the latter as in the treatment of lesions on the skin. A piece of rubber tissue 1 mm. thick is cut to fit over the entire cornea extending down into each conjunctival sulcus, is sterilized and is placed in position. Over this and in direct contact with it is placed the lead shield, over the aperture of which the radium is applied. In the author's cases the applicators have been monel metal needles containing 10 mg. each of radium element and these have been left in contact for one hour. The treatment of an epithelioma developing on the cornea differs from the treatment of hyperplasia only in the matter of dosage, the malignant lesion requiring a heavier application. The author has treated 102 cases of malignant lesions of the lid with only three failures; all the others have been cured so far as his present records have been able to follow them.

**Modification of Effects of Radon by Filtration.**—In the tissues of fourteen dogs irradiated in corresponding areas by similar doses of primary gamma radiation, but in which the filtration was 0.55 mm. equivalent of platinum and 0.8 mm. equivalent in gold, Wright observed that a peculiar periacicular formation of hyaline tissue took place over several months in the former case. Four examples of later radionecrosis had their origin in this tissue. No evidence could be found that this death of tissue resulted from any specific action of the radiation on the vasculature. It is suggested tentatively that the essential difference in irradiated tissues from normal tissues is one of reduced number of reproduction cycles, so that in the case of the more lightly filtered radiation with a greater reproduction activity in the granulation tissue around the needle this number of cycles is "used up" more rapidly than in the case of the more highly screened radiation, in which the periacicular granulation reaction is less marked and the main change is hyalinization, not a change to less mature tissue. It is indicated that the relative avascularity of irradiated tissue is the reaction of the vessels to the altered activity of the fibrous tissue rather than the result of any constricting effect by increased intercellular substance of this tissue.

Danger Signals in Artificial Pneumothorax Therapy. W. M. MacKay, Waltham, Mass.—p. 808.

**Changes in Pulmonary Tuberculosis Following Hemoptysis.**—The clinical changes observed by Reisner suggest that the pulmonary lesions developing after hemoptysis are largely the result of an extension of the tuberculous process. They are evidently caused by aspiration of tubercle bacilli and their toxic products. The importance of the hemoptysis lies in the fact that its occurrence provides particularly favorable opportunities for acute aspiration. Aspiration is a common accompaniment of hemoptysis. However, in only a fraction of cases are demonstrable pulmonary changes found. This is evidently due to the fact that the mere aspiration of a moderate quantity of blood has no deleterious effect. The

presence of aspirated blood in the bronchial tree hardly gives rise to any demonstrable changes in the roentgenogram. The conditions created by the hemoptysis and the resulting aspiration pave the way for a spread of the tuberculous lesion, as they facilitate a sudden distribution of tubercle bacilli over wide pulmonic areas. However, clinical and roentgen follow-up studies indicate that cases showing a rapid and complete resolution of the pulmonary changes resulting from hemoptysis are rather uncommon. In the majority of instances the character of the lesions indicates an extension of the tuberculous process. The various forms of posthemoptytic complications showed wide dissimilarities of the resulting pulmonary changes. The severity and the number of hemoptyses disclosed no definite relationship to a direct influence on the extent and severity of the resulting lesions. A definite parallelism was observed between the general character of the preexisting pulmonary lesion and the subsequent behavior of the spread, which indicates that the evolution and the ultimate fate of the posthemoptytic changes are determined largely by the nature of the original disease. The severest and most progressive forms of involvement were found in patients in whom the original lesion was of the predominantly exudative-caseous character with progressive destruction. The chronic protracted course and the benign evolution of the lesions resulting from diffuse aspiration are as a rule observed in instances in which the preexisting lesion is of a corresponding character. The infective dose determines the evolution and the fate of the posthemoptytic spreads. Other factors, such as variable states of allergic response and immunity, probably have an important bearing on the evolution of the resulting changes, as they may influence the effect of the spread in a favorable or in an unfavorable manner. In a group of ninety patients, widespread changes of a distinctly progressive nature had been brought about by hemoptyses in sixty. Of these, fifty-five died during the course of observation. Death occurred in thirty-five within three months after admission to the hospital, in eight between three and six months, and in eight between six and twelve months after admission. The average duration of illness for this group, from the occurrence of the hemoptysis until the fatal termination, was five months. These mortality rates indicate the deleterious effect of the posthemoptytic spread on the subsequent course of the disease and illustrate the hazards with which their occurrence is fraught. The foremost aim must be the elimination of factors that promote the occurrence of aspiration. The ill effects of the injudicious administration of narcotics, especially morphine, are referred to. The expediency of placing the patient at complete rest in the recumbent position is questioned. It would seem more appropriate to promote expectoration and ventilation by change of posture, thereby giving the patient a better chance to counteract the effects of aspiration. Artificial pneumothorax is of value in the attempt to control the bleeding and, if employed early, may prevent an extension of the disease process in the lung, particularly in cases in which the original pulmonary lesion is of a progressive and destructive nature and in which the results of aspiration following hemoptysis are frequently of a serious character. In suitable cases the pneumothorax treatment should be continued as a curative measure.

### Pulmonary Tuberculosis and Dementia Paralytica.

Leader suggests that pulmonary tuberculosis, while not common in patients with dementia paralytica, occurs sufficiently often to warrant careful observation for this condition. Recourse should be made to all available diagnostic means, particularly the x-rays, since sputum is often unobtainable. The problem of pulmonary tuberculosis in dementia paralytica is of importance not only from the standpoint of the individual patient whose therapy will necessarily be modified by the type, extent and activity of pulmonary lesion but also from the possibility of the spread of tuberculosis to others, particularly in institutions. In most cases of the present series (twelve) the syphilitic infection preceded the tuberculosis, which is in accord with the experience of many observers. When tuberculosis occurs in a person with dementia paralytica the course is not necessarily more severe than in one who does not have dementia paralytica; it may be milder, it may pursue its usual course, but it also may be more severe. Pulmonary hemorrhages have occurred following the use of tryparsamide and tryparsamide and mercury, and in at least one instance a case of quiescent

mental acute uremia and cholemia, in comparison to that of control animals. In cases of acute liver insufficiency from infarction of the liver as induced by ligation of the hepatic artery, the administration of liver extracts results in prolonging the duration of life of the animals in comparison with that of control animals. Animals that receive the extract live longer than the controls, even in cases in which the infarction involvement of the liver parenchyma is great. The author concludes that antianemic liver extracts have an antitoxic action as well as a stimulating action on the liver parenchyma, similar to that of insulin. The functions of the parenchymal areas that are not involved in the infarction process are intensified on stimulation of the extracts. The author says that more work is needed to clarify whether the actions of the antianemic extracts are due to the antianemic factor or to some other substance contained in the extracts.

 Ovulation, Menstruation and Fertility of Women According to Modern Views. F. De Luca.—p. 611.

**Action of Prehypophyseal and Cortico-Adrenal Extracts on Glycemia in Old Persons.**—According to Torresini and Nicoletti, the extracts from the anterior lobe of the hypophysis, subcutaneously injected in normal old persons, induce hyperglycemia, whereas those from the cortex of the adrenals induce hypoglycemia. They obtained these results in eight out of ten persons. The total average of hyperglycemia was 0.24 mg. per thousand cubic centimeters of blood higher than the glycemia found before administration of the prehypophyseal extract. The total average of hypoglycemia was 0.27 mg. per thousand cubic centimeters of blood lower than the glycemia found before administration of the adrenal extract. The time of appearance of the highest figure of hyperglycemia, in the several cases, varied within thirty and 120 minutes after administration of the extract. Hyperglycemic curves followed a regular ascending and descending evolution. Three hours after the test, glycemia had returned to normal or almost normal figures. Hypoglycemia was 0.15 mg. per thousand cubic centimeters of blood lower than the glycemia that existed before the test in one of the two cases which reacted with hypoglycemia to the administration of prehypophyseal extracts. The two cases which reacted with hyperglycemia to the adrenal extracts were different from those which reacted with hypoglycemia to the prehypophyseal ones. The authors believe that the hyperglycemic reaction to adrenal extracts depends on the presence of neurosympathetic disturbances originating in insufficient circulation of certain endocrine glands. Their results, as a whole, confirm those obtained in experiments. The commercial origin of the extracts used and the number of rat units (20 or 50) in the extracts did not interfere with the results.

### Minerva Medica, Turin

2: 493-516 (Nov. 24) 1936

- Hemodynamics and Permanent Slow Pulse: Cases. G. C. Dogliotti, E. Montuschi and A. Beretta.—p. 497.  
 \*Sensory and Cutaneous Vascular Disturbances from Accidental Intra-Arterial Injection of Arsphenamine. G. Sannicandro.—p. 505.  
 Genoreaction. A. Valerio.—p. 506.

**Accidental Intra-Arterial Injection of Arsphenamine.**—The intra-arterial injection of arsphenamine is a rare accident. In the only case reported in the literature (Bory's case) the accident was due to the abnormal presence of the humeral artery in the place of the vein at the elbow fold. During the injection a painful spasm of the artery was produced, which was followed by anemia of the last three fingers and consequent loss of half of the hand from secondary necrosis. Bory said that arsphenamine sets up a reaction of defense in the artery with a reflex vasoconstriction and persistent spasm, which causes necrosis. Sannicandro reports a case under the same circumstances. During the arsphenamine injection into the abnormally placed humeral artery the patient experienced an intense burning and pain in the lower two thirds of the forearm. Simultaneously with the subjective phenomena, white anemic and red hyperemic plaques, both 1 cm. in diameter, appeared on the skin of the

lower two thirds of the forearm and the hand. The general symptoms were a sense of constriction about the thorax, cyanosis, diffuse intense pallor and a decrease in the number and quality of the pulse beats, which became almost imperceptible. The patient was given some injections of camphorated oil and was left to rest in bed. One hour later, all the symptoms had entirely disappeared and there were neither immediate nor late complications. In the author's case the vascular and nervous cutaneous phenomena took place simultaneously in the cutaneous capillary territory. Because of the fact that the epithelium of medium sized arteries does not react to the passage of arsphenamine in small doses, the author believes that arsphenamine induced a vasomotor reaction in the cutaneous capillaries. His statement is based on the fact that cutaneous paresthesia from vasomotor reactions of the cutaneous capillaries is associated with local changes of the color of the skin, which correspond to the involved capillary territory. According to the author, certain vasomotor reactions of the cutaneous capillaries cause direct stimulation of the ends of the peripheral nerves. Vasomotor reactions originate in circulatory disturbances with consequent liberation of tissural substances, the rôle of which in producing cutaneous paresthesia, by stimulating the ends of the peripheral nerves, is secondary to that played by the vasomotor reaction. The author accepts the classic physiology of a direct stimulation of the ends of the peripheral nerves in the production of cutaneous paresthesia.

 \*Nonspecific Stimulation in Course of Active Specific Vaccination. P. Cotrufo.—p. 565.  
 Posttraumatic Chronic Subdural Hematoma: Case. F. Mazzini.—p. 573.

**Nonspecific Stimulation in Course of Active Specific Vaccination.**—Cotrufo studied the evolution of the processes of immunization by specific treatment following nonspecific treatment in rabbits. He found that nonspecific stimulation induced by administration of repeated injections of proteins or colloidal metals increases the defense powers of the organism. The specific reaction is more intense in animals which were subjected to nonspecific stimulation than in those which were not. Nonspecific immunization acts on specific immunization, simultaneously induced, by increasing the powers of defense of the cells that take a predominant part in the reaction to the specific bacteria. The powers of defense of agglutinins, bacteriolytic amboceptors and those related with the power of fixation of the complement increase by nonspecific stimulation in specific typhoid immunization, whereas those of reticulo-endothelial cells and phagocytes increase by nonspecific stimulation in staphylococcal immunization. Nonspecific stimulation acts by increasing the reactivity of the cells, especially the reticulo-endothelial ones, to the specific stimulation. The type of the reaction depends on the type of bacteria which causes specific stimulation. The author's results indicate that proteins injected fail to form antibodies. The latter are formed by the association of nonspecific stimulation with specific immunization.

 Action of Prehypophyseal Hormone on Gastric Secretion and Chloride Excretion. E. Fröhlich.—p. 1707.

**Diagnosis of Lupus Vulgaris.**—According to Hämel, lupus vulgaris is the most frequent form of cutaneous tuberculosis. The diagnosis of lupus vulgaris is based chiefly on the detection of the lupus nodules that correspond to a tubercle (conglomerate tubercle) deep inside the corium. They are most readily recognized by pressing the blood from the tissues by means of a glass spatula. If this is done, yellowish brown or brownish red spots become visible, above which the epithelium is either entirely unchanged or glossy and traversed by small folds. Another characteristic of the lupus nodules is a peculiar behavior in case of pressure with a probe. If such pressure

years ago Eugene Pool devised a method of systematic passive motion and exercise for the immediate postoperative patient. The nurse in attendance during the recovery of the patient should be instructed to massage the legs frequently until the patient recovers completely from the anesthetic. The patient should be encouraged to move his extremities early and often; the position in bed should be changed frequently during convalescence. In all probability patients may be confined to bed too long following operative procedures. They should be sitting up in a chair as soon as the attending surgeon feels that it is compatible with other factors. The abdominal dressing should not be tight, and full breathing should be encouraged in every possible manner. The use of thyroid extract, advocated by Walters on the theory that by stimulating all the vital processes along with the increase in blood pressure the stagnation of the venous flow is lessened, seems plausible unless otherwise contraindicated.

**Influence of Medium on Metabolism of Bacteria of Intestinal Origin.**—Hershey and Bronfenbrenner studied the metabolism of a slow-lactose-fermenting strain of the Escherichia coli type of bacteria and of its rapidly fermenting variant in lactose-containing synthetic mediums. Variation within the culture does not play any part in the early course of fermentation by these bacteria. The multiplication rate and the velocity of lactose fermentation are influenced markedly by the concentration of lactose in the medium. The effect on the rate of fermentation is direct, as well as dependent on changes in the rate of growth. The rate of fermentation varies with the bacterial population of the culture, while the rate of respiration is largely independent of it. The presence of sodium succinate as an accessory source of carbon does not appear to influence early lactose fermentation, except through its buffer effect on the  $pH$  of the culture. Succinic acid is formed from the medium more rapidly as the ratio of the concentration of succinic acid to that of lactose is increased.

**Active Pulmonary Tuberculosis Without Symptoms.**—Geer discusses a type of pulmonary tuberculosis that is not the textbook picture. On the contrary, it is that illustrated by the person who feels perfectly well, presents no symptoms, may give a history of exposure to an individual known to have positive sputum, or who has been sifted out in a Mantoux survey or has been tested by his physician in the course of a routine examination. He does exhibit a positive reaction to a skin tuberculin test and is found to have an infiltration in the chest roentgenogram usually in the first or second interspace. Rarely will these people have any abnormal physical signs in the chest. Active pulmonary tuberculosis without symptoms can be detected in most instances only by a chest roentgenogram. Its course is unpredictable and therefore requires close observation by serial roentgenograms of the chest. Aside from those persons employed in institutions, students or employees of concerns who can be followed closely, the safest and best course to follow is a period of sanatorium study.

\*Introduction of New Vegetable Concentrate in Treatment of Diabetes Mellitus. E. A. Bertucci, New Orleans.—p. 306.

**Vegetable Concentrate in Treatment of Diabetes Mellitus.**—During recent investigations and researches Bertucci has found a hypoglycemic action in the common wild thistle (Carduus), from which a concentrate is made from the stalks and leaves by a special dehydration process involving the constant recirculation of inert gases under low temperature, free oxygen being effectively excluded, thereby preserving the vitamins. The finished product is an impalpable powder. The dosage of this finished product is from 2 to 4 Gm. three times daily in capsule or powder form half an hour before meals. Just how it acts on carbohydrate metabolism is not yet exactly known. What has been gathered so far from experiments made on dogs is that it possesses physiologic stimulant properties both to the pancreas and to the liver through the possible activation of the duodenal hormone secretin. In very large doses in animals it produced an increased flow of saliva and in still larger doses emetic properties similar to ipecac but did not produce any gastro-intestinal irritation or irritation to the mucous membranes in the lower intestine. Experiments carried on during the past two years have definitely established its absolute

than in female patients, probably because of the difference in the type of breathing in each. The impairment of the respiratory function is less pronounced in patients on the regimen of early bed leaving and administration of analgesics. Protracted stay in bed appears to be an important predisposing factor in the pathogenesis of postoperative pulmonary complications. The prophylaxis of impaired respiratory function consists of pulmonary exercises, leaving bed early and administration of analgesics during the first few postoperative days.

**Renal Tumors.**—In the last four years, forty cases of tumors of the upper urinary tract were admitted to the urologic clinic of the Regional Institute of Moscow. Thirty-seven of these involved the kidney and two the renal pelvis, while one was a primary carcinoma of the ureter. Of the thirty cases in which operation was performed, twenty-three proved on histologic study to be hypernephromas, five adenocarcinomas and, of the two cases in children, one was sarcoma and one acinous carcinoma. Mayants considers intermittent symptomless hematuria with blood clots, palpable tumor and a characteristic pyelogram the diagnostic triad of renal tumor. The pyelogram is not diagnostic in itself and should be regarded as a part of the general clinical picture. Among the important secondary manifestations the author mentions a varicocele that does not disappear in the horizontal or genupectoral positions of the body, dilatation of the superficial veins of the skin of the abdomen, the presence of metastases in the lungs, bones and other organs and an increased sedimentation reaction of the erythrocytes. Excretion of indigo by the involved kidney may be normal or much delayed. Delayed excretion by the opposite kidney is due to intoxication from the involved kidney. Cystoscopic examination in a case of papilloma of the renal pelvis may reveal the tumor projecting into the ureteral orifice, and there may be threads in the urine in the absence of a tumor of the bladder. One should likewise think of papilloma in the presence of hematuria. A cystoscopic examination in the course of hematuria is indicated unless one is certain that the bleeding proceeds from the ureter or the bladder or is due to a hemorrhagic nephritis. The possibility of a metastatic hypernephroma must be kept in mind in every instance of a pathologic fracture or bone tumor. Exploratory exposure of the kidney is justified when all the urologic methods of investigation fail to confirm the suspicion of a tumor. Diagnosis of a renal tumor constitutes an indication for nephrectomy, but immobility of the tumor, cachexia and metastases of the internal organs contraindicate it. The operative mortality, as well as the late results, are considerably influenced by the early diagnosis and treatment.

Changes in Calculus Formation in Urinary Tract of Albino Rats in Some Diets, Particularly Those Rich in Calcium. P. Arons and M. P. J. van der Rijst.—p. 5652.

**Dislocations of Wrist Joint.**—In his discussion of injuries of the wrist joint, Verschuyt directs especial attention to Schnek's studies. That author maintained that a constitutional anomaly, the so-called console radius, plays a part in many luxations of the wrist joint. Verschuyt searched for this anomaly in two cases of luxation fracture of de Quervain's type, which he describes in detail, and in twelve other cases of injury of the carpus. Of the two first named patients one had this anomaly, while the other had not. Regarding the other twelve cases the author says that, of six patients with fractures of the navicular bone, four had the typical console radius and one had a mild form. Moreover, a console radius was found in three cases of necrosis of the semilunar bone, in one case of fracture of the greater multangular bone and in one case of an old luxation of the semilunar bone. In view of such a high incidence of the console radius in wrist injuries, the author thinks that this constitutional anomaly does play a part in their pathogenesis. The closed reduction method of Böhler produced satisfactory results.

**Urinary Calculi and Diet.**—Polak studied the influence of diets on the formation of urinary calculi in experiments on several groups of animals. It proved possible to produce renal and vesical calculi in nearly 100 per cent of the young white rats that were kept on the so-called basic diet II with an addition of 3 per cent calcium carbonate. In adult white rats, young white mice and guinea-pigs no calculi were formed. The administration of 3 per cent of potassium acid phosphate instead of calcium carbonate did not produce stones, nor did the addition of 3 per cent of calcium chloride. The addition of 2 per cent of calcium carbonate likewise produced stones but 1 per cent did so only rarely. Equivalent quantities of calcium lactate also produced stones, but to a much lesser degree. It was demonstrated also that the administration of sodium bicarbonate, calcium gluconate and calcium phosphate together with calcium carbonate did not result in the formation of calculi.

\*Mastopathia Cystica: Its Frequency at Postmortem Examination and Possibility of Its Spontaneous Regression. S. Lindgren.—p. 119.

**Sacral Anesthesia.**—Hellström gives an account of the mode of action and distribution of sacral anesthesia and concludes that so-called low sacral anesthesia, according to Læwen, is also largely a parasacral anesthesia. This is made evident by the author's experiments on the dead body and by clinical investigations. His own material is made up of 1,053 sacral anesthetics. In more than 900 cases he used as the anesthetic fluid 1 per cent tutocain to which epinephrine had been added. The injections have been made with the patient lying on his side. No serious complications occurred. The results were satisfactory in 87.4 per cent, fairly satisfactory in 10.1 and no anesthesia at all in 2.5. The blood pressure was studied in 100 consecutive cases. In some it was found to be increased, while in others it had fallen. The variation in the blood pressure upward or downward amounted to an average of 15 mm. The author arrives at the conclusion that sacral anesthesia is a simple, reliable and harmless method having its chief sphere of utility in endovesical and endo-ureteral examinations and operations.

**Mastopathia Cystica.**—Lindgren reviews the literature on cystic mastitis, especially with regard to prognosis and histologic appearances. Investigators who have studied specimens removed by operation for clinically observed tumors are inclined to assign to cystic mastitis a grave prognosis on account of the risk of malignant degeneration. On the other hand, authors who have clinically followed such cases diagnosed only clinically or by local excision find that carcinoma seldom develops. The comparatively few investigations on the frequency of cystic mastitis at necropsy show, with one or two exceptions, a great frequency of these changes. The author studied 120 mammary glands obtained at necropsy, the ages of the women ranging from 35 to 75 years. In some cases all the changes described as characteristic of cystic mastitis were found. He grouped his cases according to the classification of Cheate and Cutler. Cystiphorous epithelial hyperplasia was found in sixteen glands and mazoplasia in twenty-two. The rest were normal or showed simple senile involution. As many authors would probably characterize even the mazoplastic changes as cystic mastitis, the percentage frequency figures of these changes would increase further in normal women. In this material the highest frequency percentage for mazoplasia and for cystiphorous epithelial hyperplasia was found at the climacteric, but this frequency fell rapidly in the higher ages, suggesting a spontaneous regression of cystic mastitis after the menopause. The same was found to be the case in a series of tumor material of cystic mastitis but not in a series of carcinoma of the breast.

against syphilis other than by acquiring the disease itself, does antisyphilitic treatment have any effect on the resistance that would develop ordinarily in syphilitic patients as a result of their infection? And if there is any such effect, what influence should it exert on the management of such patients? The active treatment of early syphilis interferes with the orderly development of one of nature's own defensive mechanisms. Such intervention is not justified unless treatment offers something better than nature herself can offer. Persistent treatment with the proper drugs offers more than nature alone can supply. If it is not persistent, great harm may be done. Once the patient has acquired a specific resistance against the infection, treatment does not abolish the resistance and it is quite possible that it may persist long after treatment has ceased. The author is inclined to believe that it persists even after the infection has been eliminated. The evidence is that patients who have had their syphilis a long time, who are not showing any signs of the disease and whose spinal fluids are negative, have built up a fair degree of resistance to their infection and this resistance will not be overthrown at once by antisyphilitic treatment. In other words, for the patient with latent syphilis a little treatment seems to go a long way.

**Radiation-Induced Lymphopenia.**—Goodfellow performed total and differential leukocyte counts on ten patients, taking blood before and after radium treatment from the thumb and simultaneously from the area irradiated. Only patients with ulcerating tumors were chosen (fungating carcinoma of the breast, large ulcerating cutaneous epitheliomas). As a result of gamma-ray irradiation of any considerable magnitude, the following sequence of events may take place: Many lymphocytes and other leukocytes in the circulation are damaged or destroyed, and the lymphogenic and other hematopoietic centers are damaged by secondary irradiations, with or without the action of liberated leukotoxins, and the output of lymphocytes and other leukocytes into the blood stream is diminished as a consequence. To replace the deficiency of circulating leukocytes, large numbers of circulating lymphocytes may be withdrawn from the blood stream into the bone marrow, where it is possible that they develop into other forms of white blood cells. There appears to be no evidence for concluding that the lymphopenia observed during radiation therapy is in any way connected with the round-cell infiltration to be seen in and around the area affected by neoplastic disease.

**Spontaneous Surgical Emphysema in Children.**—Watkins states that spontaneous surgical emphysema in children may be congenital, a rarity occurring at birth or shortly afterward; infective, in association with gas-forming organisms; associated with laryngeal or bronchial ulceration, as by laryngeal diphtheria or foreign body, and associated with lung diseases, especially bronchopneumonia. Three cases of the last named type are reported. Study of these cases illustrates the mechanism by which spontaneous surgical emphysema arises. An acute inflammatory lesion of the lung may be accompanied by a variable amount of interstitial emphysema. If to this damaged lung an explosive force is superadded—for example, whooping cough or sneezing—there will be a tendency for the emphysematous bullae to track toward the periphery of the lung and/or the mediastinum. This may be observed if the lung of a stillborn baby is inflated forcibly; bullae will appear at the edge of the lungs and extend along the interlobular septums. Further dissection of these bullae along mediastinal fascial planes will lead to the ultimate escape of air by rupture into the subcutaneous tissues at the root of the neck. In the majority of cases this appears first on the left side in the supraclavicular region and suggests that the path of least resistance is along the tissues around the thoracic duct. There are five available methods of treatment: subcutaneous needling, collar incision, tracheotomy, artificial pneumothorax and letting nature take its course. Needling has been practiced on several occasions but has the definite risk of sepsis. Moreover, the air is absorbed ultimately and one cannot consider this a method of choice. In view of the mechanism by which spontaneous surgical emphysema is believed to arise, the most rational treatment would appear to be collapse of the lung by an artificial pneumothorax. In the cases reported, no active measures were taken to relieve the emphysema. In each instance the air was absorbed gradually and without difficulty.

In a few states it has theoretically been a responsibility of the school medical inspector to see to it that the physical defects found were remedied as far as possible, and if parents were unable or unwilling to provide the necessary treatment it was mandatory on the medical inspector to provide such treatment. This section of the law was, however, quite generally unenforced and when in the midst of the recent depression the public welfare department took over the responsibility for medical relief as well as material relief, the legal responsibility for the correction of school children's physical defects was partially if not wholly transferred from the school authorities to the public welfare authorities.

It seems very clear therefore that our law makers have to date largely conceived of our public schools as well adapted to the health education and physical education of our young but unadapted as a whole to the carrying of any serious responsibility for the medical or the dental care of the individual pupil.

There are many things to be said in favor of this legalistic concept of the public school's health and hygiene responsibilities. Such a plan guarantees that money budgeted for educational purposes is spent for educational purposes, not medical or dental purposes; it removes for all time any grounds on which might be based the accusation that the school was engaging in the practice of medicine or dentistry and thus competing with the practicing medical and dental professions.

To this traditional concept there are, however, two fundamental objections. First, from the point of view of preventive medicine it seems the acme of foolishness to go to the expense of grouping these children for educational purposes and then to throw away completely the unparalleled opportunity that this grouping affords for the application of certain preventive medical measures. For the first five or six years of the child's life he has been living at home under the supervision of parents who may or may not have availed themselves of the preventive services of family physician or health department. School entrance brings together for the first time all the children of the community and makes easily possible for the group many preventive measures that would be difficult and expensive to provide individually. Included in the list of such preventive medical services especially adapted to the school situation are group vision testing, group hearing testing, group strength testing, group posture studies, group inspections for communicable disease, and under certain circumstances group tuberculin testing, group chest roentgenographing and group urinalysis. Second, there are too many health hazards lurking in the school regimen and environment to make it safe to delimit medical supervision in this way. To take children from their life of free play and activity in the open air and place them at age 5 or 6 in a school environment where they use their small muscles of eye and hand instead of their large muscles, where mental activity substitutes for physical activity so largely, where the benefits of fresh air and sunlight are so largely lacking and the hazards of group contact and group competition are so pronounced, is obviously an unphysiologic thing to do and the lag in the growth curve that so frequently accompanies school entrance is easily explainable. Granting that the school process as preparation for modern life must consist largely of mental training, it will be a poor service done the child if his mind is developed and only a weak or diseased

body is provided to support it. Adequate medical supervision in the public school system is an absolute essential; without it the whole system of universal education for our youth becomes a questionable asset.

#### THE HEALTH EDUCATORS' CONCEPT OF SCHOOL MEDICAL AND DENTAL SERVICE

While the legal minds have been attempting to separate and to keep separated the educational functions of the public school, and the medical and dental functions of the practicing physicians and dentists, there have been many health teachers, physicians and public health workers who were quite willing to abandon the scheme of separation and attempt to place once and for all the full responsibility for the annual health examination of every school child, to say nothing of the medical treatment of defects found, on the school authorities. Thus in the Report of the Cambridge Health Education Conference, June 23-28, 1924, of the American Child Health Association is the following recommendation regarding the physical examination of school children:

I. The aim of such an examination is to provide for every child a chance to achieve the limit of his endowed capacity for well being.

II. The function of the school physician shall be:

1. To provide guidance toward better health through education of the children.
2. To provide an examination service which (1) discovers all physical defects, diseases, incipient conditions and tendencies toward ill health among school children, and (2) finds sources for remedy.

Back of these recommendations lie the best of intentions—to protect and promote the school child's health in the most certain and direct way, and with this general intention practically all social minded persons would be in accord. The real question is the question of method. To take a homely example from the field of law, one might quite conceivably favor the simplest of trials and summary execution for a self-confessed murderer in order to do justice in the most certain and direct way and with the least expense. In the long run and with all types of cases, however, a formal trial and administration of justice through the approved legal channels has been found best to protect society and the individual. The scheme of school medical service which at first sight or in the individual case might seem to be the most certain and direct way of protecting child health might in the long run so overload the school authorities with health responsibilities and so definitely diminish the health responsibilities of the practicing physicians and dentists that the child's health and education would both eventually suffer.

Such a scheme, if it actually were to attempt discovering "all physical defects" and finding "sources for remedy," would require at the least estimate one school physician for every 500 pupils. This would mean an army of 64,000 school physicians with a corresponding number of dentists, nurses, dental hygienists and other specialists. Regimentation of two fifths of the medical and dental professions in the school health program whether under education department leadership or health department leadership, would carry with it so much danger of substituting political expediency for professional efficiency as the basis of administration that most of us would be very loath indeed to see this experiment in "state medicine" tried.

anesthetized), reduced the clotting time of the blood. Large amounts could be given intravenously without producing any signs of intravascular clotting. One of the authors had repeated intravenous injections himself at varying intervals with no ill effects. Generally a single adequate dose will protect from hemarthrosis for a period varying from four days to four weeks but will control external bleeding only for from four to twenty-four hours. A dose that is adequate has to be controlled in each patient by observation on his clotting time before and after injection. There seemed to be no tendency in thirteen hemophiliac patients to intravascular clotting, however large the dose. It has in a few cases been possible, by obtaining a series of clotting time estimations at intervals after an injection, to predict fairly closely when the next hemarthrosis or bruise will occur. After its initial fall the clotting time rises at first slowly and then more rapidly. At the latter juncture an internal hemorrhage is imminent. In different patients there seems to be only a poor correlation between clotting time and bleeding tendency. It may be possible to regulate intervals of dosage by such serial estimations. In preparing the substance 40 Gm. of potassium bromide is mixed thoroughly with 200 cc. of egg white and the mixture is incubated at 37 C. for three days; 200 cc. of distilled water is added and then six volumes of 98 per cent alcohol. The mixture is filtered and from the filtrate the active material is precipitated by the addition of an equal volume of acetone; this precipitate is dissolved in water and dialyzed till free from potassium bromide, dried in vacuum at 60 C. and dissolved in a 0.9 per cent solution of potassium chloride for injection.

**Hoarseness.**—Watkyn-Thomas states that hoarseness and weakness of the voice are often found together but that the conditions are different. For the voice to be produced clearly the edges of the vocal cords must be straight and sharp. If the edges of the cords cannot meet properly, the voice will be weakened or entirely lost ("complete aphonia") according to the degree of failure of approximation. If the edges of the cords are at all roughened, even by a little crusted mucus, or if the edges are not quite sharp, the voice will be hoarse. As anything which roughens the cord produces hoarseness, it is obvious how vitally important this symptom is, for "anything" includes a little mucus at one end of the scale and a carcinoma of the cord at the other. If a patient is hoarse without remission for three weeks a laryngoscopic examination must be made. Instances in which hoarseness is the predominant symptom may occur in chronic and acute catarrhal laryngitis, tertiary syphilis of the larynx, tuberculous laryngitis and new growths of the larynx.

**Cystic Pneumatosis of Intestine.**—Chiray and Lomon discuss a case of cystic pneumatosis with associated pneumoperitoneum which they have previously reported. Cystic pneumatosis of the intestine is characterized anatomically by the existence of subserous bubbles of gas which elevate the peritoneal covering, varying from the size of a pin head to that of a nut or an egg. They are extremely numerous and give a definite aspect to the intestinal segment involved. Spontaneous recovery appears possible. The cysts contain gas and not liquid. The origin of these gaseous bubbles and of the gas which causes the distention is uncertain. Perhaps the mechanical theory is most promising. This gives some weight to the possibility that the gas is not produced at the level of the cysts or in the lymphatic system but is introduced into the lymphatic circulation because of ulceration of the mucosa. The simultaneous existence of pneumoperitoneum and of cystic pneumatosis constitutes a further argument in favor of this hypothesis. They believe that cystic pneumatosis must be considered when a patient with a previous ulcer is found to have a nonpainful and elastic abdominal distention, zones of tumefaction and painless peritoneal crepitation and when the x-ray examination reveals areas of surprising transparency resembling small vacuoles. Spontaneous pneumoperitoneum may exist with pneumatosis.

**Simple Method for Counting Platelets.**—With an erythrocyte counting pipet, Lenggenhager withdraws blood from the finger in the usual manner and dilutes it with an isotonic solution (3.8 per cent) of sodium citrate up to line 101. After thorough mixing, a drop (but not the first one) is put into the erythrocyte counting chamber. The count is taken at once. The author stresses that the withdrawal of blood should not be too slow, since this might result in a partial agglutination of the platelets. He also emphasizes that the citrate solution should be sterile and should be centrifuged before each use. As the advantages of the method he stresses first its rapidity. It can be completed in from ten to fifteen minutes, because neither staining nor sedimentation needs to be awaited. Other advantages are the direct counting in the chamber, which permits the counting of the erythrocytes in the same specimen, and the great exactness of the method.

**Antitoxic Action of Liver Preparations Containing the Antianemic Factor.**—Schiappoli carried out studies to ascertain the antitoxic and antihemolytic action of liver preparations containing the antianemic factor. He was able to show that the antianemic extracts do not hinder hemolysis induced by hypotonic solutions in vitro. On the contrary, they have a direct hemolytic action. They do not have antitoxic action on exogenous toxins. They fail to cause a reaction of the type produced by the detoxicating hormone (yakitron) in exogenous acute experimental poisoning. They have antitoxic action against endogenous toxins. They give satisfactory results in grave chronic liver insufficiency, control coma in atrophic cirrhosis, and increase the duration of life of animals in experi-

might be properly geared in with the other preventive medical services of our states and communities (i. e., orthopedic services, tuberculosis services, social hygiene services, mental hygiene services, communicable disease services), this plan would almost of necessity provide that a bureau or division of school medical service be set up in each state department of health and that this bureau or division have general charge of the supervision over the school medical service.

Plan 2 would assume that the practitioners of medicine and dentistry will in time adequately provide the annual health examination. It would divide the responsibility for preventive medical services for school children between the practicing physicians and dentists on the one hand and the school on the other hand. This division of services would be worked out as follows:

1. The thoroughgoing annual medical examination and the preventive inoculations to be considered important parts of the family practitioner's "stock in trade" and as such to be frankly left in the general practitioner's hands except as outlined (6 a and b).

2. The thoroughgoing dental examination and cleansing to be considered important parts of the family dentist's "stock in trade" and as such to be frankly left in the family dentist's hands except as outlined (4 a and b, 6 a and b).

3. For each school district there is to be made available each year a school physician whose supervisory duties should be:

(a) General supervision over school efforts to control communicable diseases through exclusion of cases and observation of contacts.

(b) Prescribing exercises for and maintaining general supervision over those children needing restricted or special corrective exercises (in cooperation with the family physician).

(c) Passing on all illness excuses from physical education.

(d) Reviewing of health texts submitted for school adoption to determine the scientific accuracy of their facts.

(e) Conducting a sanitary survey of the building and grounds at least twice a year.

(f) Supervision over though not actual care of injuries to school athletes.

(g) Supervision over care of swimming pool.

(h) Supervision over effort to notify parents through notes and home visits regarding unremedied physical defects of their children and to acquaint them with all facilities available in the community for the remedying of these defects.

(i) Supervision over the responsibility for physical fitness of athletes participating in strenuous sports.

4. For each school district there is to be made available each year a school dentist or dental hygienist whose duties should be:

(a) To provide oral inspection of all children at entrance and in grades 3, 5, 7 and 10 (or in some similar sequence).

(b) To provide inspection of any children specially referred by teacher or nurse.

5. For each school district there is to be made available each year a school nurse whose duties should be:

(a) Aiding the physician in his medical inspections.

(b) Conducting limited health inspections.

(c) Notification of parents regarding physical defects.

(d) Visiting parents to urge corrections.

(e) Cooperation with social welfare agencies to obtain correction of defects in indigent families.

(f) Provision of nurse's first aid.

(g) Home visits in selected cases for checking of illness absences.

(h) Sanitary inspection of school plant weekly.

(i) Cooperation with public health authorities in obtaining examination of adults in homes of tuberculin-positive children.

6. In the school there is to be provided a limited health inspection service as follows:

(a) Health inspection by nurses and teachers annually with reference of culled cases to the school physician or dentist for further study.

(b) Medical inspection by school physicians and dentists at entrance and in third, fifth, seventh and tenth grades (or in

some similar sequence) with additional special group tests (such as audiometer hearing tests and tuberculin tests) given at strategic intervals only but planned to make a cumulative whole of the child's twelve year school medical record. (See chart.)

#### PLAN 2 PREFERABLE

Plan 2 is preferable in my opinion because it would leave the annual health examination in the hands of the general practitioners of medicine and dentistry and yet it would effectively utilize the school grouping of children for preventive medical purposes.

In favor of plan 2 also is the fact that it is in substantial agreement with the recommendations of the Subcommittee on Medical Service of the White House Conference on Child Health and Protection<sup>5</sup> and with the recommendations of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association.<sup>6</sup> The summarized report of the Subcommittee on Medical Service of the general Committee on the School Child of the White House Conference stated:

The examination at school cannot be expected to be as thorough as that made by the family physician. Usually the school routine will be a partial examination—a physical inspection from a medical viewpoint. This should be done in a manner that will create a confidence in all concerned and develop a favorable attitude toward an annual examination.

If, however, the assumption is to be made that the practitioners of medicine and dentistry will in time adequately provide the thoroughgoing annual health examination, there should be valid reasons for that assumption. I would advance the following reasons:

1. Since increasing knowledge of disease brings increasing ability to prevent disease, it is only logical to expect that there will be a steadily increasing emphasis on the preventive functions of medical practice. This will very likely mean that periodic health servicing (including medical examining, preventive inoculations, and health-habit inventorying) will gradually replace a great deal of the emergency medical treatment as carried on by the medical profession today.

2. Certain of the medical colleges, as for example Yale, are frankly building their curriculum around the preventive function in the practice of medicine. When we get a new generation of physicians specifically trained to meet their preventive medical responsibilities, the outlook for real health servicing in the hands of the general practitioner will become promising indeed.

3. The lay public is becoming very rapidly aware of the fact that the medical and dental professions could if they would provide a preventive medical and dental service which would lengthen life and avoid a great deal of pain and disability. The public is already demanding this service in increasing numbers. If additional effort to create this demand were made by our insurance companies, by our official and nonofficial public health organizations, and perhaps by our state and local medical societies, this demand could quite possibly be made universal.

#### HEALTH DEPARTMENT VS. EDUCATION DEPARTMENT LEADERSHIP

In the organization of our public school system today it is generally assumed that whatever activity is to be carried on in our schools must be carried on under the

is exerted on the epidermis covering the lupus nodule, the probe sinks into the tissue under slight bleeding, owing to the softening of the tissue by tuberculous changes. Lupus nodules may greatly resemble acne nodules or nodules of follicular rosacea, but differentiation is nevertheless possible, since in rosacea there always exists dilatation of the superficial vessels and acne vulgaris is accompanied by comedones. However, the differentiation of lupus vulgaris from syphilis, particularly from late syphilis, is often extremely difficult. This may have serious consequences for the patient, because the syphilitic process may cause as much destruction in weeks or months as lupus vulgaris does in years. Another means of differentiation is that in lupus new nodules may form within the scars in case of relapse, whereas in syphilis this is extremely rare, for here the focus usually heals in the center, while there is a constant serpinous progress on the edges. Internal treatment with potassium iodide is helpful in the differentiation: in late syphilis this treatment results in a rapid breakdown of the inflammatory changes. In the presence of tuberculosis of the internal organs, a cutaneous disorder is often regarded as of tuberculous nature. This is not justified, because the concurrence of tuberculosis of internal organs with other skin diseases is not at all rare. The differentiation between lupus vulgaris and lupus erythematoses may prove difficult. The latter is not of a tuberculous nature. The detection of lupus nodules will permit the diagnosis of lupus vulgaris, whereas lupus erythematoses is characterized by bristle-like or nail-like projections on the cutaneous scales. In taking up other forms of tuberculous skin diseases, the author points out that lupus miliaris is often mistaken for acne vulgaris or follicular rosacea but can be correctly identified by the presence of lupus nodules. In tuberculosis cutis verrucosa, however, lupus nodules are absent. This form of cutaneous tuberculosis often develops after accidental injuries. It may be mistaken for chronic pyoderma, but a prolonged tuberculosis cutis verrucosa is characterized by a sieve-like appearance of the disease focus and, whereas pyodermias yield to treatment with sulfur, mercury and so on, tuberculosis cutis verrucosa does not. Tuberculous scrofuloderm is usually readily identified.

**Significance of Sedimentation of Erythrocytes.**—Reichel first stresses the importance and the simplicity of the sedimentation reaction and then discusses the method, emphasizing particularly the importance of the length of the test tube. Especially in case of rapid sedimentation the height of the blood column must be taken into consideration. An accelerated sedimentation is observed (1) in all inflammatory processes, (2) in case of necroses and cellular disintegration and (3) in case of parenteral resorption of protein. The author points out that the determination of the sedimentation speed is a nonspecific reaction like fever and leukocytosis. In healthy persons the sedimentation speed is never accelerated. If examination of a patient does not reveal an organic disorder, a sedimentation test should be made. If it shows acceleration, a more careful examination will reveal a cause for the acceleration. On the other hand, normal sedimentation speed is not necessarily a sign of health, for the sedimentation speed is accelerated only if the protein composition of the plasma is changed.

\*Cardiac Asthma and Bronchial Asthma. M. Weinberger.—p. 1373.

Conservative and Surgical Treatment of Goiter. F. Kaspar.—p. 1377.

Cultural-Social Conditions of Our Time and Neuroses. M. Minkowski.—p. 1379.

Silicosis. L. Teleky.—p. 1382.

**Cardiac Asthma.**—Weinberger designates as cardiac asthma an especially characteristic form of cardiac dyspnea. It differs from the ordinary dyspnea of patients with heart disease by a

sudden, paroxysmal, occasionally unfounded and often nocturnal appearance. It may occur also during the day, after work or excitement. Moreover, it may complicate an already existing cardiac dyspnea. After citing the aspects that differentiate cardiac asthma from Cheyne-Stokes respiration and from angina pectoris, the author points out that the attacks of cardiac asthma differ in duration and intensity. In the mildest forms the attack disappears after a few minutes and the patient falls asleep again, but during subsequent nights he is awakened by the same attack. Many patients fear the attack and abstain from eating in the evening, because they have experienced that a meal before retiring increases the attacks. Frequently râles can be heard over the lower parts of the lung and occasionally the signs of pulmonary edema develop. If this is the case, the attack may end fatally in persons who formerly were apparently healthy. Cardiac asthma is most frequent in patients with hypertension, atherosclerosis, nephritides, mesaortitis and myocardial disorders, whereas in valvular lesions it is less frequent. From this the author deduces that it occurs chiefly in case of insufficiency of the left side of the heart and is rarer in defects of the right side of the heart. He reviews the literature on the pathogenesis of cardiac asthma, emphasizing Straub's opinion according to which there exists in cardiac asthma a disturbance in the chemical and the reflectonervous regulation of the heart and of the peripheral circulation and that the attack may be elicited from various sites. In discussing the treatment of cardiac asthma the author points out that narcotics, particularly morphine, have often been recommended. The administration of small doses of morphine in the evening often prevents the nocturnal attacks. During the attack he advises the subcutaneous or intramuscular injection of from 1 to 2 Gm. of morphine to which from 0.5 to 1 Gm. of atropine has been added. Spasmodic remedies in the form of heat or medicaments have been recommended as substitutes for the narcotics. In pulmonary edema an intravenous injection of 40 cc. of a 40 or 50 per cent solution of dextrose is advisable. In order to improve the heart action, digitalis preparations or strophanthin may be required. Measures that reduce the nocturnal load of the circulatory apparatus on the part of the water economy (dry diet) are of prophylactic value.

**Leaving Bed Early After Operation.**—Khromov investigated the vital capacity of 250 patients subjected to an operation. The method consisted in determining the vital capacity two days before the operative intervention and daily during the postoperative period until the return of the vital capacity to normal. In 100 of the patients an appendectomy was performed, in 100 a herniotomy and in fifty various operations away from the abdominal cavity. Local anesthesia was used in all cases. There was an equal number of men and women in each group and the ages ranged from 18 to 50 years. The three operative groups were subdivided each into two subgroups. One subgroup was kept in bed for a period of six days after herniotomy and for five days after appendectomy and operations away from the abdomen. The second subgroup was subjected to the regimen of early bed leaving, in most cases on the first and at the latest on the second day. The percentage of diminution of the vital capacity in the three subgroups on the regimen of protracted stay in bed was 48, 40 and 13 for men and 36, 32 and 7 for women. The reduction of vital capacity in the subgroups subjected to the regimen of early bed leaving amounted to 35, 30 and 5 per cent for males and 20, 20 and 0 per cent for females. There were seven instances of postoperative pulmonary complications in the first group and only one in the second. The author concludes that operative intervention, particularly within the peritoneal cavity, lowers the respiratory function of the lungs and that the regimen of protracted stay in bed plays a part in it. This is more pronounced in male

Indeed, we find that when we perform Heller's test with an aqueous solution of phenolphthalein sodium we obtain a turbidity in dilutions down to 5:10,000. The turbidity thus produced is not in the form of a distinct ring, as is the case with the albumin precipitate, but rather is dispersed through the upper layer of fluid: for freshly precipitated phenolphthalein is quite readily soluble in strong nitric acid.

Robert's reagent, being more sensitive, gives a turbidity in solutions of phenolphthalein sodium down to 2.5:10,000. The turbidity disappears when the solution of phenolphthalein sodium contains only 1:10,000.

When urine is saturated with crystalline phenolphthalein, no reaction is obtained, even with Robert's test, obviously because the solution is too dilute; for urine of  $p_H$  7.5 does not dissolve more than 1 part per hundred thousand.

On the other hand "colloidal" phenolphthalein,<sup>3</sup> which is much more soluble than the crystalline form, when added to urine to the point of saturation does give a very definite trace of turbidity with Heller's test and a strong ring test with Robert's reagent.

For differentiation between true albuminuria and this ring test due to phenolphthalein, advantage may be taken of the fact that phenolphthalein solution when heated does not become turbid even when acetic acid is added. On cooling, a turbidity may result which disappears again on heating. As, in the presence of albuminuria, heating produces a turbidity that increases on the addition of acetic acid, the differentiation is easy.

Having thus fortified ourselves with the ability of distinguishing between true albuminuria and a possibly false reaction due to the presence of phenolphthalein, we might as well report the fact at this point that in the entire range of our 1,000 observations on urines after medicinal doses of phenolphthalein we did not encounter a single instance of a false albumin test due to phenolphthalein. This is because the total amount of phenolphthalein in the urine, both free and conjugated, never approaches the quantity necessary for the production of the phenolphthalein ring when its solution is layered over an acid reagent.

#### METHOD OF STUDY

The specimens of urine were obtained from male medical students at the University of Illinois College of Medicine and from male patients at the Cook County Hospital. Specimens from women were largely excluded because of the possibility of confusing contamination of the urine from such sources as postmenstrual discharge.

The following tests were employed as a routine on each of the urine specimens.<sup>4</sup> The standard methods described in textbooks were employed for the various albumin tests and in testing for sugar in the urine. Turbid specimens of urine were filtered until clear.

**Determination of Free Phenolphthalein in Urine.**—Ten cubic centimeters of urine was treated with 10 cc. of absolute alcohol and 1 cc. of 10 per cent sodium hydroxide. For comparison we used a standard solution in the same quantity of distilled water, alcohol and alkali, to which was added the suitable standard solution of phenolphthalein to the point of color equality. The

phenolphthalein standard may be 1 per cent, 0.1 per cent or 0.01 per cent, depending on the quantity of phenolphthalein in the specimen. The original color of the urine was compensated for by a solution of 10 cc. of urine, 10 cc. of alcohol and 1 cc. of water. A comparator block was used for evaluation of the color.

The twenty-four hour specimens of urine that were preserved with xylene were treated differently. Since phenolphthalein is somewhat more soluble in xylene than it is in urine, it was detected, if at all present, by shaking out the xylene with tenth normal sodium hydroxide volumetric solution, the phenolphthalein imparting a pink tint to the sodium hydroxide solution. Free phenolphthalein was not determined quantitatively in such twenty-four hour specimens, as the xylene of the twenty-four hour urine was not all available and the result therefore was expressed as 0, slight trace (sl. tr.) or trace (tr.).

**Determination of Conjugated Phenolphthalein in Urine.**—Five cubic centimeters of urine and 5 cc. of 10 per cent hydrochloric acid were heated on a water bath for two hours. This was shaken out with 25 cc. of ether in several portions. The combined ether portions were then shaken out with 10 cc. of tenth normal sodium hydroxide volumetric solution. The color produced was matched with that obtained with 10 cc. of tenth normal sodium hydroxide volumetric solution and a standard phenolphthalein solution (containing 0.01 Gm. in 100 cc.) to the point of color equality.

**Determination of Acidity by Folin Method.**—Twenty-five cubic centimeters of urine was placed in an Erlenmeyer flask, treated with 1 to 2 drops of 0.5 per cent phenolphthalein solution and shaken with 15 to 20 Gm. of potassium oxalate and immediately titrated with tenth normal sodium hydroxide volumetric solution with constant shaking until a pronounced pale rose color appeared. From this we calculated the number of cubic centimeters of tenth normal sodium hydroxide solution required to neutralize the total twenty-four hour quantity of urine and employed this figure in our tabulation.

#### OBSERVATIONS ON NORMAL INDIVIDUALS

Advantage was taken of the opportunity to secure the cooperation of medical students, men ranging in age from 20 to 26. In each case a preliminary specimen of urine was secured and then the subject was given a capsule containing a medicinal dose of phenolphthalein, with the direction to take it at bedtime and to secure all the urine passed during the succeeding twenty-four hours, to mix the various specimens, to measure the total quantity, and to furnish a sample of the mixed urine for testing. In order to prevent decomposition of the urine, which would interfere with the determination of its acidity, xylene was added to the specimen, and this was taken care of as described.

It would serve no good purpose to burden this report with the results of 650 observations of this kind, which were consistently negative on chemical as well as on microscopic examination of the urinary specimens both before and after the taking of phenolphthalein. An idea of the amount of labor involved in this study might be gathered from the fact that it required more than 10,000 tests of various kinds. In any one individual at least a week was permitted to elapse between succeeding observations. It might perhaps suffice to report (table 1) eight individual cases typical of the entire series. The meaning of the symbols at the head of the columns have been explained in a footnote in table 1.

## AN APPROACH TO THE PROBLEM OF SCHOOL MEDICAL AND DENTAL SERVICE

D. F. SMILEY, M.D.

Medical Adviser and Professor of Hygiene, Cornell University  
ITHACA, N. Y.

Late statistics show that in the United States there are now in operation 245,941 public schools housing 26,849,639 pupils. In these public schools \$8,000,000,000 has been invested, and to maintain this property and support the 1,055,825 teachers and other school personnel an additional \$2,000,000,000 is expended each year. Adding the private and parochial school registration figures to the public school figures gives a total of 32,031,549 children attending schools of elementary and secondary level.

In view of the fact that society has at considerable expense thus grouped our 32 million children for purposes of instruction, the question quite naturally arises: To what extent are we utilizing the school grouping of these children to improve their health and their hygiene?

To answer this question, one would naturally look first to the legal requirements set up in the various states regarding (1) school medical supervision, (2) health instruction and (3) physical education.

### LEGAL REQUIREMENTS

J. F. Rogers<sup>1</sup> reported legal requirements for school medical inspection in 1930 as follows:

In all, thirty-eight states have some kind of a statute or regulation (usually a statute) either permitting or requiring the examination of children for physical (and sometimes mental) defects. . . . Examinations are "required" annually (presumably of all pupils) in twenty states; every two years in two and every three years in one. . . . A physician is specified as examiner in five states, the county health officer in three states, while in twenty the physician is mentioned as one of the examiners. . . . In three states a nurse is apparently the only examiner . . . and in fourteen others she may participate in examinations. Examination by teachers is specified by mandatory laws of seven states though usually for specified conditions. . . . It is stated that the teacher may be one of the examiners in eleven other states. . . .

In three states examinations of children seem to be limited to those of sight and hearing; in one to sight, hearing and breathing; in one to sight, hearing, nose and throat; in one to sight, hearing, breathing and teeth; in two to dental defects; while a more general examination is specified in fifteen.

With regard to health instruction, Rogers<sup>1</sup> summarizes the various state requirements as follows:

While the requirement of instruction in the effects of alcoholic drinks and of narcotics (tobacco is mentioned in many of these

statutes) was the first intent of these laws, it was recognized that such teaching belonged as part and parcel to the larger subjects of physiology and hygiene and these more general branches are required without limitation as to content by forty states.

Concerning state requirements for physical education or big muscle activity programs, W. F. Meredith<sup>2</sup> gives the following summary:

Thirty-seven states have enacted laws relative to physical education. Of these, thirty-three make health and physical education mandatory in all or part of the schools of their states. In addition to these, two of the eleven states not having laws have established mandatory requirements.

In general, the legal requirements of the various states may be summarized as follows: Every state requires in its schools instruction with regard to the effects of alcohol and narcotics, forty states require the teaching of physiology and hygiene, thirty-three states make physical education mandatory as part of the school program, twenty states require annual physical examination and three require such examination only periodically (every two or three years).

### THE LEGALISTIC CONCEPT OF SCHOOL MEDICAL AND DENTAL SERVICE

Underlying these legal requirements is the assumption that each child has outside of his school life (1) parents to advise him and guide him with regard to his health and hygiene, (2) a family physician and a family dentist to provide periodic health servicing and medical and dental treatment and advice as necessary, (3) a health department to protect him as far as community efforts can from the hazards of communicable diseases, (4) a home in which to be taken care of in periods of minor illness, and (5) a hospital for bed care in case of major illness. Assuming the existence of these facilities in the home and the community, the responsibility of the school for the health and hygiene of the child is quite definitely limited and restricted in the minds of the legislators who drew the laws summarized in the preceding section. The intent quite definitely is to leave the major responsibility for the health and hygiene of children with the parents and the family physician, the school taking on only such health responsibilities as are almost unavoidable; i. e., examination of eyes and ears to make sure that the child's tools for learning are at least in usable condition, and such communicable disease control measures as are necessary to maintain a respectable average daily attendance and to prevent the school's becoming a "hotbed of infection" in the community. The intent on the health teaching and physical education side of the program is, however, quite definitely to accept the school's responsibility and make provision for meeting it.

mental light of known and planned intensity. In addition, the first reading in the recovery period offers valuable information concerning the ability of the subject to regenerate visual purple during exposure to the light. During the light period visual purple is being bleached and regenerated at the same time. These two processes come to an equilibrium within three minutes under the conditions of this test. Adequate vitamin A permits rapid regeneration even in the light. If the subject could regenerate visual purple as rapidly as the

Fig. 5.—Values for a subject who is objectively night blind but who is not aware of night blindness.

light bleaches it, he should require no more light for the first reading in the recovery period than for the last reading in the foreperiod. With the light intensity used in this test no one has yet shown such rapid regeneration, though a few subjects have been encountered who had initial recovery values as low as 0.1 millifoot candle. The first reading in the recovery period represents the resultant of two effects, namely, the bleaching and regeneration of visual purple. Since the intensity of the light and the time of bleaching are the same for all subjects, the difference in this reading with different individuals is a measure of their relative rates of regeneration of visual purple during the stimulus of light. Therefore the reading assumes considerable importance in the evaluation of the results of the test.

When a large number of people are subjected to this test and the results are plotted, the different curves obtained will vary in the manner shown in figure 3. The curves of those with excellent dark adaptation approach a straight line, the degree of approach, of course, depending on the scale of plotting. Conversely, the curves of those with the poorest adaptation depart farthest from a straight line. The most significant points of departure are those of the recovery period, and of these the greatest change is found in the first reading in the recovery period. Though the change late in the recovery period is of lesser degree, it is often highly significant, especially when the final values are greater than 0.1 millifoot candle.

With curves of all degrees of departure from a straight line, an appraisal becomes necessary to determine which are normal and which are not. The appraisal is assisted by noting the type of curve given by those who have been ingesting an abundance of vitamin A. Vitamin A produces improvement in the readings in the direction of a smaller light requirement. However, they improve only to a minimum value which is relatively constant for the same individual but which varies in different individuals. It seems reasonable to consider as normal all results from those known to have had a high intake of vitamin A and who do not

have detectable uncorrected ocular defects. From the experience gained with this test up to the present and on the basis stated, we would place the upper limit of normal at 0.6 millifoot candle for the first reading in the recovery period. It is possible that the results obtained subsequent to the ingestion of an abundance of vitamin A are supernormal or high normal and that the range accepted as normal should be increased. It is certain, however, that readings should not be accepted as normal because they are average. Readings which are only slightly greater than those stated as normal are classed as borderline. Somewhat empirically we have set the upper limit of borderline at approximately 1 millifoot candle. When the first reading in the recovery period is greater than this, it is classed as subnormal.

Dark adaptation increases rapidly in the recovery period. The speed and degree of increase may be observed in the plotted curves of figure 3. Those with normal adaptation have final readings of less than 0.05 millifoot candle. The only exceptions encountered are in those instances in which the visual threshold is increased by causes other than vitamin A deficiency. Those subjects who are classed as borderline also may have final readings within the limit of 0.05 millifoot candle, or slightly more light may be required; but in either event the high point of the curve is reached less quickly than in the normal curve. In figure 4 are shown two curves which are considered borderline. One of these has its fault chiefly in the first reading of the recovery period and the other chiefly in the later readings. If either the first or the last readings were considered alone as criteria, many abnormalities would be overlooked. The entire recovery curve is considered important.

In the subnormal group are to be found all degrees of impairment of dark adaptation. Those with lesser degrees of impairment are not subjectively aware of

Fig. 6.—Test results showing improvement obtained in ten and sixteen days respectively with 20,000 units of carotene daily.

any difficulty, while others with very poor photometer readings recognize their abnormality. In those with subjective night blindness the first reading in the recovery period may require as much as 7, 8 or more millifoot candles, and at the end of the ten minute recovery period from 0.4 to 0.5 millifoot candle may be required. The latter values represent a state in which the subject is visually quite helpless in the outdoor darkness of night. However, some improvement is to be expected with the lapse of a longer time than the ten minute dark period of the test. A wide zone seems to exist between the curves of those whom we have classed as borderline and the curves of those who

### THE PRESENT STATUS OF SCHOOL MEDICAL SERVICE

A sufficiently accurate picture of school medical service as it is found today is presented in a recent report of the Committee on School Health of the American Academy of Pediatrics:<sup>3</sup>

We have had the physician and the nurse in the schools long enough so that the public, the teachers, the administrative officers, and the boards of education would not do without their assistance. They want to know the physically handicapped children. They want the medically neglected child cared for. They want advice and assistance when communicable disease threatens. Any school staff which has had a little of their assistance wants more than can be supplied. This demand has led to a practice of rapid selection of children who seem to need medical care. This practice has been almost universally used for over twenty years. The need for this screening service is established, but the method of screening has been extravagant and ineffective. It has used the physicians to follow routines that are wasteful and unscientific. It has been the horrible example of the physician employed by a government agency. The physician, pressed by lay officials to see more children than he can effectively examine or appraise, obviously violates the principles laid down by the House of Delegates of the American Medical Association.<sup>4</sup> "The responsibility for the character of medical service" has not been "borne by the profession." The operation of the service has not been according to medical standards. "We have allowed the demand for seeing large numbers to lead us into hasty and dubious judgments instead of adhering to the principle that the medical profession alone can determine the adequacy and character of medical service." We have allowed the public or the school authorities to push us into attempting hasty judgments that we know were not based on sound medical standards.

This indictment of school medical examinations needs no elaborate evidence of current practice. Thousands of physicians who have tried conscientiously to render this service have testified to the hasty and unsatisfactory examinations they have been required to make. Many have given it up in disgust. Thousands more now engaged in this work are willing to give similar testimony but are unable to change the system. There is sufficient recognition of the unsatisfactory character of the medical and nursing service in the schools by educational and public health leaders to insure a cooperative response for well considered plans for improvement.

In a recent paper, Dr. Donald B. Armstrong, president of the National Health Council, stated that "the school medical program as now conducted is in general one of the least efficient of our public health procedures."

### THE FUTURE OF SCHOOL MEDICAL SERVICE

Few of us would like to see the legalistic concept of separating medical and educational services pushed to its logical conclusions. Few of us on the other hand would like to see the school completely taking over the responsibility for the medical and dental care of our school children.

Between these two extreme positions there is a middle ground on which we might build conservatively and safely. But even in building on this middle ground we must make certain assumptions and choose between two quite different plans. Back of both plan 1 and plan 2 would lie the general assumptions that:

(a) All medical and dental treatment should be eliminated from the schools and left squarely in the hands of the practitioners of medicine and dentistry, with the public welfare department acting as the intermediary in indigent cases.

3. Mitchell, H. H.: Forty Years of School Medical Inspection, Report of the Committee on School Health of the American Academy of Pediatrics, J. Pediat. 7:714 (Nov.) 1935.

4. Amendments to Principles of Medical Ethics, Proceedings of the Cleveland Session, J. A. M. A. 102:2118 (June 23) 1934.

(b) All the educational phases of health work should be given due place in the school curriculum; i. e., health habit training, the inculcation of health knowledge, posture training, the development of interests and skills in the various forms of exercise and recreation, the development of an appreciation of the importance of a thoroughgoing annual medical and dental examination, of what constitutes a balanced diet, proper illumination, adequate ventilation, a normal amount of sleep and rest, and so on.

Plan 1 would assume that general practitioners of medicine and dentistry will never of their own accord and without governmental aid adequately provide for the annual health examination. It would therefore adopt the preventive part of the recommendation of the Cambridge health education conference and frankly socialize the preventive medical services, including medical and dental examination, school nursing service and general health servicing for all children during their school life just as we have socialized certain preventive medical services for our communities in our public health departments. It would allocate approximately 32,000 physicians (one to each 1,000 school children)

Suggested plan for school medical and dental inspections (plan 2):  
M. I.: Medical inspection by physicians, to include (1) eyes and lids (observation); (2) ears, canals and drums (with speculum); (3) nose (with speculum); (4) teeth and gums (without mirror); (5) throat and mouth (with tongue and depressor); (6) lymph nodes (palpation); (7) thyroid (palpation); (8) heart (auscultation and palpation of apex) before and after exercise; (9) lungs (auscultation of inspiration after deep expiration and cough, in eight spots on the chest); (10) nutrition (observation and palpation); (11) skin (observation and palpation); (12) orthopedic defects (observation); (13) posture (observation, alignment of spine to vertical surface); (14) hernia (palpation on cough); (15) feet (observation); (16) nervous system (eliciting of simple reactions and observation); (17) speech (observation).

H. I.: Health inspection by nurse or teacher, to include (1) height (height rod); (2) weight (scales); (3) visual acuity without glasses (Snellen test), right, left; (4) visual acuity with glasses if worn (Snellen test), right, left; (5) hearing acuity (watch test), left, right; (6) complaints suggestive of illness (questioning); (7) signs suggestive of illness (observation).

D. I.: Dental inspection by dentist or dental hygienist, to include (1) inspection of teeth (mirror and explorer); (2) inspection of gums (mirror and explorer).

First special vision test: Snellen and/or Ferre and Rand (Bausch & Lomb), Betz (Keystone).

Check inoculations: History of diphtheria inoculations, history of scarlet fever inoculations, history of smallpox vaccination, inspection of smallpox vaccination scar.

Special hearing test: 4a audiometer test of all, 2a audiometer test of selected cases, otologic examination of selected cases.

Second special vision test: Snellen, and/or Ferre and Rand, Betz, Ishihara color vision.

Tuberculin Test: Mantoux, intradermal; 0.10 mg. Saranac old tuberculin or 0.00002 mg. purified protein derivative; chest roentgenogram of positive reactors.

Chest roentgenogram: flat film (acetate or paper) of chest of each child not already roentgenographed within three years.

and corresponding numbers of nurses and dentists or dental hygienists to this school medical service at an annual cost of from \$5 to \$10 per child. (In but few states is even \$1 per child being spent annually on school medical service, but even an annual expenditure of \$10 is not unthinkable, especially in those states in which the annual school cost per child is something over \$100.) In order that medical leadership might be guaranteed for this army of physicians, nurses and dentists, and in order that the school medical service

poor dark adaptation is to make only the first reading in the recovery period; this procedure is not suitable for a survey but serves to find quickly a group of subnormal subjects for experimental study.

#### EXPERIMENTAL VARIATIONS OF THE TEST

Many variations of the test have been tried in the attempt to determine the most useful procedure. The bright light of the photometer has been altered in intensity by the use of 50, 75, 100, 150 and 500 watt bulbs in turn. Different periods of exposure to the bright light have been used. The distance of the eyes from the quincunx screen has been varied. Different lengths of foreperiod have been tried. The test has been conducted with the omission of the foreperiod.

It was found that illumination more brilliant than that supplied by the 100 watt bulb is frequently uncomfortable. Even the light of the 100 watt bulb is unpleasant to those who have night blindness; some normal subjects report blinking of the eyes for a period of from twenty to thirty seconds. When brilliant illumination is used, the effect is too great and the bleaching of visual purple too intense for a useful test procedure, even when the period of exposure is much shortened. As compared to the more brilliant illumination, the milder effect of the 100 watt lamp permits

Fig. 9.—Results of repeated tests of the same normal subject.

the demonstration of a finer distinction in the difference between individuals in their ability to regenerate visual purple during the bleaching period. The 50 and 75 watt lamps do not produce as much effect as is considered desirable and most useful in the test. When the 100 watt lamp is used, the light intensity at the plane of the eyes during the test is the same as that of the test previously reported.

In varying the time of exposure to the bright light it was found that an equilibrium between degeneration and regeneration of visual purple is reached in approximately two minutes. Thus, the first reading of the recovery period is the same whether the exposure has been for three, four or five minutes and in many instances for two minutes. In order to shorten the time consumed by the test, the original five minute exposure has been shortened to three minutes. The period of three minutes rather than of two minutes was chosen in order to make certain that the critical point has been passed.

It has been found that lengthening the foreperiod beyond ten minutes does not change the results. This finding is important in those instances in which it is desired to keep subjects waiting in the dark for the test.

#### EXPERIMENTAL ERROR

With almost every biologic procedure, exact duplication of results is difficult and not always to be expected. When the same individual is tested repeatedly with the

biophotometer the curves obtained may coincide, but more often slight differences are to be observed. These differences are always greater with the first reading of the recovery period than with subsequent ones. They are greater for those with subnormal than with normal readings. Children offer more difficulties than do adults. They are easily distracted and the presence of more than one child at a time in the dark room often interferes with the test. On one occasion it was found that the waiting child was giving the answers for the child being tested. Especially when working with children under 11 or 12 years of age, more accurate results are obtained by giving a preliminary test as a trial or practice procedure in order to give the subject a general idea of what is desired. Practice not only aids in giving more consistent readings but also in some degree tends to improve them in that slightly less light is required for the end point.

It seems probable that much of the difference that is found in the first reading of the recovery period with successive tests on the same subject is to be explained on the basis of timing of the reading. The technic permits a variation of ten seconds in obtaining this reading. This variation is at a time when adaptation is occurring at a rapid rate. Despite the factors that have been mentioned, the variations in the first recovery reading are small for normal subjects. For subjects in whom adaptation is subnormal the first recovery reading tends to be more variable, but it remains subnormal.

For the final reading of the recovery period the time consumed in making the test is relatively unimportant. The variations are within a narrow range for normal subjects. The percentage of variation may be large, as for example from 0.01 to 0.03 millifoot candle as shown for the subject of figure 9, but this variation, when charted, appears small. As with the other readings of the test, the final recovery reading shows greater variation in those with subnormal adaptation, though the differences are not as great as in the first reading of the recovery period.

Figure 9 illustrates the results of successive tests of a boy of 11 years over a period of three months. This case is selected only because of the larger number of observations on the same individual. The subject was receiving a diet relatively low in vitamin A with no supplemental source of this material. Despite the variations found, the readings are within normal limits in all instances.

Occasionally are encountered bizarre curves or curves which do not conform to the expected or usual contours. Explanation for these usually is not difficult. An emotional disturbance, such as fear of the dark, causes wholly unreliable results. A desire to please, which leads to guessing or to giving hasty answers, is quickly detected. The closing of the eyes during exposure to the bright light is usually indicated by the shape of the curve. Illness or indisposition affects the results adversely. Some young children have difficulty in making a decision as to what they see and the results are not dependable. Increased experience in giving the test tends to eliminate errors from these various sources. It is believed that, when the technic is carefully followed and allowance is made for such disturbing factors as have been mentioned, the experimental error is not great enough to interfere with proper interpretation of the test results.

direct and undivided authority of properly trained and appointed school superintendents and principals. Since the child's school day contains only a definite and limited number of hours, it is argued that it would make for difficult administration to have two totally independent departments, i. e., health and education, both in full authority to make demands for that same time.

The disadvantages accruing to education department leadership are, however, as follows:

1. Superintendents and principals tend to look to physical education teachers rather than medically trained persons to head up their school health programs (largely because the former are full-time employees and have credits in education theory, administration and supervision which carry more weight with many school administrators than do medical, dental or nursing degrees). This creates a situation which is unacceptable from the medical point of view—physicians working in the schools under directors of physical education who, coming up through the fields of gymnasium instruction or athletic coaching, have no interest in and no knowledge or appreciation of the principles of preventive medicine.

2. State departments of education, instead of turning directly to their state department of health for supervision over their school medical service and thus utilizing a state supervisory staff, oftentimes already in existence for orthopedics, social hygiene, mental hygiene, communicable disease, tuberculosis, and the like, tend to set up a second supervisory staff. This is not only wasteful in its duplication but it is deplorable in that it bars the health department with its more complete organization permanently from a field of service among children grouped for the first time where it could make perhaps its greatest contribution.

If the really important matter is to keep school administrative problems simplified, we must all vote for education department leadership. If, however, the important matter is really to utilize the school grouping to give each child the best society has to offer both as to education and as to preventive medicine, certainly the advocates of health department leadership have a right to be heard.

If plan 1 should be adopted I would not hesitate to state that health department leadership for the school medical and dental service was essential in view of the size of the medical job contemplated. If plan 2 should be adopted I would still be inclined to favor health department leadership, but I would not feel that success for this plan was by any means impossible under education department leadership.

#### CONCLUSIONS

1. On the principle that "the shoemaker should stick to his last," our legislatures have more or less consistently separated medical functions from educational functions and have made but little if any place for a medical program in our schools.

2. At the other extreme are those who would gladly see our schools taking over the responsibility for the medical and dental care of the school child, examining, diagnosing and correcting defects, just as they have taken over the responsibility for the education of the child.

3. A plan is presented (plan 1) which would definitely allocate to the school but under the state department of health the preventive medical services for children of school age. This could be done at a not

prohibitive cost per pupil, but it is open to the serious objection that it would take from the general practice of medicine and dentistry a considerable part of its "stock in trade" and transfer one fifth of the medical and dental professions from general practice to regimentation and bureaucracy.

4. A plan (plan 2) is presented which would eliminate all medical and dental treatment from the schools, develop to the maximum the educational phases of health work, leave the annual medical examination and preventive inoculation in the family practitioner's hands, and set up a system of school medical supervision and limited health inspection.

5. Plan 2, in my opinion, would serve as an effective means of utilizing the school grouping of our children for improving their health and hygiene, supplementing, not substituting, for the work of the general practitioners of medicine, and without inordinately increasing the cost to the community or regimenting any large proportion of the medical profession.

## PHENOLPHTHALEIN STUDIES

### A THOUSAND DOSES OF PHENOLPHTHALEIN: URINALYSES

BERNARD FANTUS, M.D.

AND

J. M. DYNIEWICZ, Ph.G., Ph.C.

CHICAGO

Most textbooks on pharmacology and therapeutics give phenolphthalein a clean "bill of health" as far as its effect on the kidney is concerned. Thus Sollmann<sup>1</sup> states: "The kidneys are not irritated, nor are there any other systemic effects." Bastedo<sup>2</sup> says: "In extensive clinical use of the drug with frequent urine examinations there has been no albuminuria." There are, however, some textbooks on the subject which report that phenolphthalein has produced albuminuria. The literature on the subject, which will be reported on later in this article, is in a similar condition: for, while nearly all authorities on the subject find phenolphthalein harmless to the kidney, there are a few reports extant that would suggest an opposite possibility.

In consideration of the enormous consumption of phenolphthalein by our people, possibly three billion doses a year, the question whether phenolphthalein produces albuminuria or damages the kidney in any way is so important a matter of public hygiene that it seems to deserve a searching investigation. To put this question to a crucial test, the study of a thousand medicinal doses of phenolphthalein was undertaken with special scrutiny of the effect on the urine.

#### PHENOLPHTHALEIN RING TEST IN URINE

It seemed possible a priori that one might encounter a false albuminuria reaction owing to the fact that acidification precipitates phenolphthalein from its solution in alkaline fluids. Since many of the albumin tests depend on acidification, this possibility had to be ruled out.

From the Laboratory of Pharmacology and Therapeutics, University of Illinois College of Medicine and the Cook County Hospital.

Because of lack of space, this article has been abbreviated here by the omission of tabular matter. The complete article appears in the authors' reprints.

1. Sollmann, Torald: *A Manual of Pharmacology*, ed. 3, Philadelphia, W. B. Saunders Company, 1926, p. 230.

2. Bastedo, W. A.: *Materia Medica, Pharmacology, Therapeutics, Prescription Writing*, ed. 2, Philadelphia, W. B. Saunders Company, 1918, p. 134.

poor dark adaptation; two gave results classed as borderline. Thus 76 per cent of the children gave normal results and 24 per cent did not. The children with poor photometric readings were given vitamin A under supervision at school. At the time this is written the children have been receiving vitamin A for a period of one month. All except three have attained normal test readings. The three who have not yet responded have had careful and expert ophthalmologic examination, and no organic cause for poor dark adaptation has been found. It is tentatively assumed that ultimate recovery will occur.

#### THE VITAMIN A REQUIREMENT

A few observations have been made in an attempt to determine the vitamin A requirement. Several children with poor dark adaptation were placed under care in the hospital metabolism ward and given a controlled and measured diet which permitted a daily intake of from 5,000 to 6,000 units of vitamin A. These children promptly improved in their adaptation ability and had normal photometric tests. On another occasion two children, 11 years of age, were placed under similar care and given a diet which permitted the daily ingestion of 3,000 units of vitamin A. The one child who had a normal test in the beginning continued normal during three months of this regimen (fig. 9). The other child, subnormal in the beginning, had approximately normal tests after two months (fig. 10). Thus for these two children it may be concluded that 3,000 units of vitamin A is adequate when the photometric test is used as the criterion. For the first diet, which contained from 5,000 to 6,000 units, the amount of vitamin A was estimated, though the food was measured. This diet simulated closely the diet regularly received by our hospital children except that it contained no concentrated source of vitamin A. For the diet that contained 3,000 units the amount of vitamin A was determined by assay. It is recognized that the group of children studied is too small to permit conclusions as to a general applicability of the observations, but nevertheless they seem of interest.

#### SUMMARY

A new photometer and a technic for its use in the determination of ability to adapt to darkness have been developed.

The intensity of the light with which the photometric readings are made is controlled by a rheostat, which is calibrated in terms of millifoot candles; this permits the results of one investigator to be compared with those of another, a procedure generally difficult for dark adaptation tests.

Evidence has been obtained for considering the test a useful means for detecting vitamin A deficiency.

Comparison of the results with the new technic with those of our formerly reported procedure shows certain defects of the old test, though the principle on which it was based seems sound.

Of twenty-three children of an orphanage eight, or 35 per cent, had abnormal test results by the new technic. A survey of a group of thirty-seven local school children showed 19 per cent to be subnormal and 5 per cent borderline. These results confirm those of the previously reported survey in that they indicate that vitamin A deficiency is more frequent than has been generally assumed.

Observations on two boys 11 years of age indicate that vitamin A in the amount of 3,000 units daily meets their requirements as judged by the photometric test.

## KETO-CHOLANIC ACIDS IN THE MEDICAL MANAGEMENT OF LOW GRADE GALLBLADDER DISEASE

CLARENCE F. G. BROWN, M.D.

Associate in Medicine, Northwestern University Medical School  
and St. Luke's Hospital

AND

RALPH E. DOLKART, M.S.

Searle Fellow in Clinical Medicine, Northwestern University  
Medical School  
CHICAGO

The rôle of gallbladder disease in the production of upper abdominal distress and of "dyspeptic" complaints is well recognized. Blackford and Dwyer<sup>1</sup> in 1924, reporting a series of 1,650 cases presenting gastric symptoms, found that the organic pathologic condition of the abdomen causing the "dyspepsia" involved the gallbladder in 52 per cent of the cases. Crump<sup>2</sup> in 1931, reporting a series of 1,000 routine postmortem examinations, found signs of chronic and healed cholecystitis in 300 cases. He concludes that upward of 40 per cent of the adult population have disorders of the biliary system.

Despite the widespread frequency of chronic cholecystitis, the principles of therapy are highly controversial. Judd, Crisp and Waldron<sup>3</sup> state that, according to the present conception of chronic cholecystic disease, some change in the gallbladder wall represents the seat of the trouble and that removal of the organ is the only way to eradicate the primary factor. They conclude that almost all cases, especially those presenting stones, constitute a surgical problem. The fact remains however that, according to Stanton,<sup>4</sup> in approximately one third of all operations undertaken for the relief of symptoms diagnosed as of gallbladder origin no stones are found. Furthermore, in Stanton's series of ninety stoneless cases followed for an average of three and one-half years after cholecystectomy, there was no demonstrable effect on the morbidity in 47 per cent of the cases. These figures compare favorably with those reported by other investigators.

Innumerable methods of medical management have been proposed—the Lyon duodenal drainage, the dietary regimen and others. Rehfuess and Nelson<sup>5</sup> go so far as to state that the demonstration of gallbladder disease by physical examination, cholecystogram or duodenal drainage is an indication for the low fat, low cholesterol dietary management. Magnesium sulfate as a cholagogue, vegetable cholagogues such as emodin, disinfectants supposedly eliminated in the bile such as salicylates and hexamines, and various decholesterolizing substances have all been suggested. Restriction of fats in conjunction with cathartic medication is the commonly employed form of therapy. Under such managements we have found that the patients feel better for a while, but sooner or later a recurrence of the gallbladder syndrome is ushered in after a period of loss of weight, loss of strength, and the appearance of symptoms of a markedly irritable bowel.

In the column headed "dose," the figures refer to fractions of grams and the letters to the variety of phenolphthalein administered:

- A = Experiment with white phenolphthalein.
- B = Experiment with yellow phenolphthalein.
- C = Experiment with colloidal phenolphthalein.

It might possibly be well to explain at this point that by "white phenolphthalein" we mean the crystalline phenolphthalein described in the U. S. Pharmacopeia.

Yellow phenolphthalein is a product developed in the course of manufacture of phenolphthalein consisting of a mixture of this body with about 2 per cent of as yet unidentified colored bodies, some of which are drastically purgative. In the subsequent purification by crystallization from alcohol, these colored bodies remain in solution. Studies are in progress on the nature of these substances.

Colloidal phenolphthalein<sup>3</sup> is produced by precipitating a solution of phenolphthalein sodium by means of carbon dioxide in the presence of a protective colloid such as gelatin. This product is unstable in liquid form, but it may be secured in the form of a scale preparation by drying it in a thin layer and at a low temperature in the presence of enough acid, such as citric acid, to prevent reversion to the colored sodium salt by loss of carbon dioxide. This product is considerably more soluble than the white phenolphthalein, as is shown by the fact that it will dissolve in a solution of sodium bicarbonate ( $p_H$  8.2) in which crystalline phenolphthalein is insoluble.

One may conclude as a result of these 650 observations that in all these individuals no albuminuria resulted from the doses of phenolphthalein given.

#### CASES OF ALBUMINURIA IN SUPPOSEDLY NORMAL INDIVIDUALS

The exceptions to the proposition just laid down are shown in tables 2, 3 and 4, in which we report all cases of albuminuria discovered in the course of this study on students. They may be divided into three classes:

Class 1. In one case (table 2) albuminuria was present in the morning specimen as well as in the twenty-four hour specimen, before as well as after the taking of the phenolphthalein. This is obviously an individual with a somewhat pathologic kidney, and there is no evidence that the phenolphthalein increased the damage.

Class 2. In two cases (table 3) we found albuminuria in the twenty-four hour specimen, before as well as after the taking of phenolphthalein. As these men had no albuminuria in the morning specimen, we have here evidently cases of "orthostatic albuminuria." It will be noted that the albuminuria was inconstant and that it had no relation to the taking of phenolphthalein.

Class 3. An occasional and very inconstant reaction to Robert's reagent was encountered in five cases (table 4). This was very irregular and generally occurred only once in all the various observations made in a particular individual. The fact that the other protein tests were negative stamps these reactions as due to proteose rather than to protein; in view of its inconstancy, it must be considered an adventitious admixture. It certainly had nothing whatever to do with the taking of the phenolphthalein.

It may be concluded that in not one of these instances could the albuminuria or proteosuria be ascribed to the taking of the phenolphthalein.

#### HOSPITAL CASES

To determine the reaction of sick individuals and especially of persons somewhat advanced in years, the kidneys of some of whom might presumably be more sensitive to injury, we studied a series of patients in the nose and throat service, including the Head Cancer Clinic at the Cook County Hospital, as well as of some patients in medical wards. We may summarize our observations by saying that in all 150 of these patients who had no albuminuria before the administration of phenolphthalein in doses of from 0.1 to 0.5 Gm. there was not a single case of albuminuria. It required about 4,500 tests to develop this conclusion.

A series of forty-four patients who had albuminuria before the administration of phenolphthalein was also studied, and it was found that in no instance was there any evidence of increase in the albuminuria or microscopic evidence of change in the urinary sediment excepting in one case. In this patient, who was under treatment at the hospital for renal colic and whose urine contained a trace of albumin before the phenolphthalein was given, there appeared blood and albumin in the urine together with the symptoms of renal colic the day after the dose was administered. Whether the taking of the phenolphthalein had anything to do with precipitating the kidney colic is debatable. It is certain that it had nothing to do with the formation of the stone or the appearance of the blood and albumin in the urine. It should be noted here that a case similar to this one has been reported in the literature and uncritically ascribed to a phenolphthalein reaction by Holz,<sup>5</sup> who reports his own case as follows:

Having taken, in the course of six weeks, seventeen "purgen" tablets with very satisfactory results, I took a half tablet one evening and awoke the next morning with severe pain in the left hypogastric region, which was not relieved by stormy bowel evacuation. Nausea and meteorism developed, accompanied by chills and colicky pains, accompanied by a peculiar burning pain in the left kidney region which, especially on urinating, extended into the external urinary meatus. The urine became red and showed albumin and red blood corpuscles but not casts on microscopic examination. Opium suppositories relieved the pain. There was obstipation for two days followed by an evacuation of gas and bowel movement. The albumin disappeared from the urine within six days.

This attack, which to a clinician is highly suggestive of a typical attack of renal colic, Holz ascribes to "intestinal occlusion due to irritation and inflammation of the colon with spastic contraction as well as left-sided kidney disease due to purgen poisoning," as though one kidney could be singled out for attack by a poison circulating in the blood stream.

Interesting in connection with this study are those cases that presented albuminuria before the taking of phenolphthalein and in which the urinary condition improved after the dose as indicated by the reduction in the amount of albumin in the urine and the disappearance of the albumin reaction in a number of cases. We report these examinations in table 5. From it, it is obvious that there certainly was no kidney injury in any of these cases, and, if the diminution of the albumin or its disappearance is any indication, there might have been an improvement of the condition.

In all these cases there was no evidence of kidney damage or the production of albuminuria due to the administration of phenolphthalein.

pital Outpatient Department, a second group was studied in cooperation with Drs. Franklin S. Wilson and S. P. Cromer at the University of Illinois Research Hospital. Similar methods of study and treatment were employed in the two clinics. All patients were ambulatory during the study. This report deals with the results obtained in the treatment of sixty-five cases of chronic cholecystitis by the methods here described.

Four general roentgen classifications were made for the purpose of the investigation: (1) nonvisualizing gallbladders with no roentgen evidence of stones, (2) nonvisualizing gallbladders with stones, (3) normally visualizing gallbladders with stones, (4) gallbladders manifesting delayed emptying.

All patients were followed at frequent intervals by cholecystographic examination. This objective evidence, together with subjective changes, constituted the two criteria of evaluation of the results of therapy used in this investigation. The original groups were reclassified after treatment according to (1) both subjective and roentgenologic improvement, (2) subjective but no

The various dietary managements employed were those used as a routine in the clinic. The hourly feeding schedule was identical with that prescribed as a routine in the management of peptic ulcer.

#### RESULTS

The results of this study appear in the accompanying table. Two hundred and twenty-one gallbladder visualizations were performed on a total of 131 patients in the course of this investigation. Sixty-five patients were accepted for the series.

It will be seen that the most consistent subjective improvement occurred in those patients receiving the keto-cholanic acids. In the majority of instances the subjective improvement was found to parallel the objective improvement, as revealed by repeated cholecystographic examination. The exceptions to this general observation were those patients in whom large stones had been demonstrated. These patients manifested marked improvement subjectively, but little change could be observed roentgenologically. In some cases

#### Response to Various Forms of Therapy

Roentgen Classification	Results of Therapy	Types of Therapy*						
		I	II	III	IV	V	VI	VII

\* I indicates hourly feedings and antispasmodics; II, hourly feedings and keto-cholanic acid; III, hourly feedings, keto-cholanic acid and antispasmodics; IV, bland diet and keto-cholanic acid; V, bland diet, keto-cholanic acid and antispasmodics; VI, low fat, low cholesterol diet only; VII, low fat, low cholesterol diet, keto-cholanic acid and antispasmodics.

roentgen improvement, (3) roentgen but no subjective improvement, (4) no improvement, either subjective or roentgenologic.

In order to control the study properly, seven variations in therapy were employed: (1) hourly feedings and antispasmodics, (2) hourly feedings and keto-cholanic acids, (3) hourly feedings, keto-cholanic acids and antispasmodics, (4) bland diet and keto-cholanic acids, (5) bland diet, keto-cholanic acids and antispasmodics, (6) low fat, low cholesterol diet only, (7) low fat, low cholesterol diet, keto-cholanic acids and antispasmodics.

The keto-cholanic acids<sup>15</sup> used in this experiment consisted of a mixture of 3, 7, 12 triketocholanic acid, 3, 12 diketocholanic acid, 3 keto-cholanic acid and 3, 7 diketocholanic acid. The mixture of the foregoing keto-cholanic acid contained the oxidation products of all the natural bile acids found in human bile in their normal proportions. Administration was orally in the form of 3¾ grain (0.24 Gm.) tablets. One tablet was given three times a day, making a daily dosage of 11¼ grains (0.72 Gm.). In four patients in whom no improvement in visualization was observed following sixty days of this medication, the dosage was doubled.

15. The keto-cholanic acids used in this investigation were especially prepared for us and furnished by G. D. Searle & Co., Chicago.

in which multiple small stones were reported, the roentgen report on the first examination was non-visualization. Following the dietary and keto-cholanic acid therapy, the gallbladders were found to visualize and the filling defects due to stones were noted at this time.

In a few cases in which stones were reported on the first Graham-Cole test, they were not in evidence on succeeding visualizations, following keto-cholanic acid therapy. The chief point to be emphasized, however, is the marked subjective improvement with concomitant roentgen improvement in so many cases.

No adverse results were obtained in any of the groups receiving the keto-cholanic acids. Only four patients in the series failed to improve subjectively. Three of the patients with nonvisualizing gallbladders had normally visualizing gallbladders after therapy. Interesting results were obtained with those patients who gave histories of frequent repeated attacks of typical gallbladder colic. After approximately two weeks of therapy the attacks would decrease in severity and frequency and gradually disappear.

In three instances untoward results were obtained when we began the hourly feedings of milk and cream and the keto-cholanic acids simultaneously. One patient reported increased distress with pain in the upper right

are subjectively aware that their ability to see in the dark is abnormal. This difference may be only apparent rather than real, as the complaint of night blindness usually is not stated unless the difficulty causes a serious handicap. In figure 5 are shown the results of a test of a young adult who does not have any subjective sense of night blindness yet who has been observed objectively by companions to have difficulty in keeping to a path at night which the remainder of the group could see readily. The plotted curve of this subject

Fig. 7.—Effect of carotene administration to a subject whose original curve was classed as normal.

shows relatively greater departure from the normal in the last than in the first reading of the recovery period. Detailed ophthalmologic examination of this subject revealed nothing more than myopia, which was fully corrected with lenses.

#### THE PHOTOMETRIC TEST AS A MEASURE OF VITAMIN A DEFICIENCY

Adaptation of the normal eye to darkness depends on the ability to regenerate visual purple, which in turn is related to the presence in the retina of vitamin A or a closely related substance. Consequently, any test that shows relative or absolute capacity for dark adaptation becomes a test for vitamin A deficiency in those with potentially normal eyes. This fact is readily demonstrated by the administration of vitamin A or carotene to those with poor adaptation and no gross uncorrected visual defect. Normal adaptation has been attained repeatedly by this procedure in our study material; one instance is illustrated in figure 6. Even those with normal adaptation may show some improvement when vitamin A is administered. However, in such instances the test results soon reach a point beyond which no further improvement is to be noted. In figure 7 are shown the test results of such a subject.

In order to demonstrate adaptation changes rapidly in our studies, relatively large amounts of concentrated preparations of vitamin A or carotene have been used. When administered in excess in this manner, no difference has been noted between the effects of carotene and those of the fish liver oils. This probably may be accepted as an expected result despite implications in the literature that the vitamin D content of the fish liver oils is a factor in the improvement of dark adaptation.

It is essential to recognize that poor dark adaptation may result from causes wholly unrelated to vitamin A deficiency. In such instances adaptation can be improved by vitamin A therapy only to the extent that the subject is deficient in this vitamin. In figure 8 are shown the test results for three subjects with retinitis pigmentosa, all of whom had been ingesting vitamin A in addition to the usual diet. One of the three curves shows only a moderate divergence from the normal. This is accounted for on the basis that the degenerative

change in the retina has not yet affected the fovea in significant degree, an explanation supported by the finding of a vision of 6/6 in both eyes with correction and visual fields of from 15 to 25 degrees for a 5 mm. test object at 120 cm.

With possibly rare exceptions the ocular defects responsible for poor dark adaptation are revealed by ophthalmologic examination. These abnormalities are found with greater frequency in a medical clientele than in the general population. It is believed that, at least among children, the proportion of abnormal test results produced by causes other than vitamin A deficiency is statistically unimportant in surveys made in the general population, especially when those with obvious ocular defects are excluded.

#### BRIEF TESTS FOR RAPID SURVEYS

Shorter tests than the one described are advantageous at times, especially in large surveys when the total time consumed assumes importance. However, an abbreviated test should be employed only after considerable experience has been acquired in conducting the test in the usual manner. The foreperiod or preliminary period in the dark is considered desirable, but readings during that period are not important except as they accustom the subject to the procedure and thus permit more accurate readings later. Thus, one subject can be waiting in the dark while another is being tested. A reading should be made at the end of the foreperiod and the test continued as already described. If desired, the duration of the test may be reduced still further by decreasing the recovery period to six or seven minutes.

Fig. 8.—Test results of three subjects with retinitis pigmentosa.

The data thus obtained are usually sufficient to show the type of curve and the ability to regenerate visual purple. Subjects who have abnormal readings by any of these procedures should be given the longer test, but normal results usually would not be changed by the longer test. A rapid method of finding subjects with

to find any report of serial pressure readings at intervals after encephalography that would warrant an authoritative opinion as to the course of the spinal fluid pressure during the period of intense headache.

Although ordinary room air is most frequently used for encephalography, other gases have been offered as substitutes from time to time, without, however, any very definite claims of advantage. Liberson<sup>4</sup> found carbon dioxide to be absorbed too rapidly for proper visualization.

Nitrogen showed no superiority to filtered air, but he felt that helium possessed slight advantages over either. Zeller<sup>5</sup> employed the insufflation of acetylene as a therapeutic measure in meningitis but was not concerned with the visualization of the ventricular system.

The use of anesthetic gases for encephalography was first proposed by Aird<sup>6</sup> in 1934, when he reported an experimental series in dogs. The advantages he hoped

space. My aim has been to maintain a relatively constant spinal fluid pressure rather than to attempt a volume for volume replacement. Fluid is allowed to flow out of the lower needle in 10 cc. portions, following each of which gas is injected to bring the pressure in the manometer up near the original value. This is the only feasible method in which readily soluble gases are used, since frequently in order to maintain a constant pressure it is necessary for the amount of gas injected to exceed the amount of fluid removed by as much as 50 per cent, owing to solution of the gas during the injection.

Eight encephalographies were done with nitrous oxide. The radiologic results were good in three, fair in four and poor in one. Filling of the ventricles was generally satisfactory, but so rapid was the absorption of the gas from the subarachnoid channels that they were very poorly visualized.

Since nitrous oxide was absorbed too rapidly for good radiologic results, it was decided to change to ethylene, which, as can be seen from table 1,<sup>7</sup> is only one-fifth as soluble as nitrous oxide although still seven times as soluble as air.

To date I have done thirty encephalographies with ethylene. In twenty-four of these the visualization of the ventricles and subarachnoid channels has been excellent, in five only fair and in one poor. In this case, however, a subsequent trial with air yielded no better results. A survey of 189 encephalographies done with air showed no higher percentage of satisfactory results. Because of the fairly prompt disappearance of subarachnoid ethylene, it is essential that the x-ray examination be made immediately following the injection, as a delay of as little as fifteen minutes may result

to gain were twofold: anesthesia or analgesia from the local action of the injected gas, and more rapid absorption of the gas. In the employment of nitrous oxide and ethylene he felt that he accomplished both of these objectives without adding to the hazards of the procedure. He has shown definitely that absorption is more rapid, as the gas disappeared from the ventricles in but one hour with nitrous oxide as compared with seven days with air. His criteria of production of analgesia are less definite, as the animals were subjected to moderate doses of morphine or amytal before the encephalography, while at best the evaluation of the amount of headache suffered by a dog must be rather difficult. Aird felt, however, that definite analgesia was produced both by nitrous oxide and by ethylene.

So favorable was the experimental trial of these two gases that in March 1934, a month after Aird's report, I did my first encephalography with nitrous oxide in man.

I have utilized as a routine two lumbar punctures for encephalography, allowing the fluid to escape into a graduated cylinder from the lower needle, which is provided with a side arm for connection with a water manometer. The upper needle is provided with a three-way valve, one arm connecting with the bore of the needle, the second with a sterile rubber bladder containing the gas to be injected, and the third with a 50 cc. syringe. By manipulation of the valve, gas may be drawn into the syringe from the gas bladder and expelled through the needle into the subarachnoid

in poor visualization. This necessity for expedition will, however, be appreciated by the patient, who consequently is returned more promptly to his bed.

The headache complained of during the injection of the gas did not, in my opinion, differ in kind or degree from that experienced by patients in whom air was injected. Naturally, no exact measure of this symptom was possible, and clinical observation was my only aid in judgment. Nevertheless, it is probable that I was

COMPARISON OF THE PRESENT TEST WITH  
ONE PREVIOUSLY REPORTED

The principle on which the previously reported test<sup>1</sup> was based is the same as that of the present test. The results of continued observation indicate that this principle is sound. Further study by means of the new photometer permits a clearer picture of the phenomena involved, and in the light of this newer information certain defects of the older test become evident.

The Birch-Hirschfeld photometer of the old test and the biophotometer of the new test have different characteristics. The Birch-Hirschfeld instrument is more complicated in that both the wedge and the diaphragm must be manipulated to make a reading. These procedures permit an exact reading within the range of the instrument, but they require an amount of time considerably greater than for a reading with the new photometer. The time required to make the first reading in the recovery period is highly important if this reading is to have significance. When the Birch-Hirschfeld readings are compared with those of the biophotometer in terms of light values, it becomes apparent that adaptation has advanced to a marked degree by the time the first reading of the recovery period is made with the Birch-Hirschfeld instrument. Thus a subject who is classed as borderline or moderately subnormal by the new test because of the first recovery reading may appear normal by the old test. This discrepancy has been observed in several instances in which the two tests were applied to the same subject. When the first recovery reading is poor by the Birch-Hirschfeld instrument, however, it is still poorer by the biophotometer. Thus the biophotometer reveals a higher proportion of moderately subnormal subjects than the Birch-Hirschfeld instrument.

When the final readings of the recovery period are obtained by the two photometers and compared in the same manner, it appears that the readings agree within the range of experimental error, since the time factor in making this reading is not so important as for preceding readings. Such differences as occur are to be explained in a large measure by the finer gradations of measurement permitted by the new than by the old photometer. The changes in the amount of transmitted light are by relatively gross steps in the Birch-Hirschfeld instrument. It has been brought out elsewhere in this publication that subjects who are classed as borderline or moderately subnormal often have final readings within the normal range, the divergence from normal being in the earlier readings. Thus dependence on the final readings alone would cause to be missed many abnormal individuals. If the final reading is poor, however, it is significant even when considered alone.

Several statements in our first publication on this subject may be interpreted as attaching importance to the amount of the difference between the first and the last readings. From the discussion of the new test in this publication it becomes obvious that the greater differences between the first and last readings of the recovery period are shown by those with subnormal adaptation.

## A REVIEW OF OUR FORMER SURVEYS

The data of our former surveys have been reviewed in the light of more recently acquired information and experience. With only two exceptions the final readings of all the children were definitely poor when the first reading was poor; in these two the final readings

were borderline. Consequently little error seems to be introduced into these data by the omission of the first readings and by consideration of only the final ones. When the distinction between normal and abnormal is rather finely made, the results are essentially identical with those which were reported. When a larger and perhaps more reasonable degree of experimental error is allowed, the proportion of children with definitely subnormal adaptation becomes 10 per cent less in each instance. For example, the 26 per cent subnormal stated for the rural group becomes 16 per cent and the proportion of borderline cases increases from 10 to 20 per cent. It is to be recognized that if these figures are acceptable at all they must be considered as minimum, because abnormality is often missed when only final readings are used as the basis of classification. Whatever incidence of vitamin A deficiency may finally be determined for the population of this country, it seems clear to us that it is greater than has been heretofore generally assumed.

Fig. 10.—Results of successive tests of a boy who originally had a subnormal curve but whose test results became approximately normal while he was receiving a diet containing 3,000 units of vitamin A.

## SURVEYS AMONG CHILDREN

Much intensive study has been made of the new technique now being reported and several hundred children and adults have been tested, some of them many times. The objective has been the perfection of the test and a study of its usefulness. Of the many individuals tested, only two small groups can be considered as representing controlled surveys.

During the latter part of August and the early part of September 1936, while the test was being studied with orphanage children as subjects, it was applied to twenty-three children who were living together in the same cottage and who can be considered as comprising an unselected group as far as the orphanage is concerned. Of these twenty-three children eight, or 34 per cent, had subnormal test results.

In the month of October 1936, thirty-seven children of the third and fourth grades of a local school were examined. These children ranged in age from 7 to 10 years. Those who had abnormal or peculiar results were retested, the number retested being fifteen. It was found that one child had very poor and six had

## ABSTRACT OF DISCUSSION

DR. J. JAY KEEGAN, Omaha: Encephalography has become a fairly well established aid in neurologic diagnosis. However, as cited by Dr. Newman, it is a disturbing and sometimes a dangerous procedure, owing to the irritating effect of the air injected. Any improvement in technic that will reduce this reaction will be welcomed by both patient and physician and Dr. Newman's trial of ethylene gas instead of air is to be commended. Experience has taught that, in brain tumor suspects either with increased intracranial pressure or with impaired consciousness, disturbing reactions to an injection most frequently develop and complicate case management or desirable surgery. It is inadvisable to operate on these patients until they have fully recovered from the depression and temperature reaction that usually follow. There probably are two factors in the disturbing reaction of the meninges to air or other gases. One is the mechanical alteration in tension caused by the shifting and perhaps expanding air bubbles within the small meningeal spaces. This may account for some of the immediate reaction after about 20 cc. of air has entered. The second source is the irritating effect of the gas used, as evidenced by the consistently increased cerebrospinal fluid cell count. This irritation may cause immediate painful vascular spasm and later some tissue swelling. The longer the air remains, the longer will the irritation be continued; and ethylene gas, because of its more rapid absorption, appears to reduce the duration of the inflammatory reaction. Another application of such a readily absorbed gas would seem to be in ventriculography. Since encephalography carries additional hazard in cases with increased intracranial pressure and is contraindicated in cerebellar tumors, resort must be made to bilateral occipital trephine and replacement of ventricular fluid by air. The lateral ventricles in such cases usually are dilated to some degree and considerable air must be injected to visualize properly by x-rays both lateral and third ventricles. It is my impression that the reaction is due more to the disturbance of ventricular pressure rather than to the irritating effect of the gas. These patients have initial high ventricular pressure, and shock may occur from simple withdrawal of ventricular fluid. Furthermore, the suboccipital block remains and pressure recurs within six to twelve hours after the air injection, possibly in greater degree because of some tissue swelling. It has been my routine practice to tap these ventricles repeatedly after ventriculography, to permit air escape and control of the recurrent pressure. When this is done it is surprising sometimes how little immediate or subsequent reaction these patients show from ventriculography.

DR. MABEL G. MASTEN, Madison, Wis.: Since Dandy's introduction in 1919 of this most widely used procedure, modifications and improvements have been made, and every phase of the subject has been thoroughly investigated. Eight deaths (five of them brain tumors) in 3,200 encephalograms performed at the New York Neurological Institute speak eloquently for the safety and usefulness of encephalography. While many operators do not use narcosis, desiring the cooperation of the patient and depending on sedative and analgesic drugs, others prefer complete anesthesia. Waggoner and Himler advocate nitrous oxide anesthesia; ether is used at the Mayo Clinic, while Lessinger and Scarff at Bellevue and at the New York Post-Graduate Hospital are enthusiastic over tribrom-ethanol, overcoming postural difficulties of the unconscious patient by a specially designed frame. The most debatable question in encephalography has been the method of withdrawal of spinal fluid and its replacement by gas. Frequent manometric readings guide the operator in not exceeding the limits of normal intracranial pressure. A mortality of four (two in the last six months) in 1,200 encephalograms at Wisconsin compares favorably with Dyke and Davidoff's and emphasizes the safety of a simultaneous and practically a volume for volume replacement system. Whether drainage is complete or partial is a minor point. All who are active in encephalography are aware of the pressing need for improving two features: (1) the discomfort during and succeeding the procedure; (2) the shortening of the period of hospitalization. Those who employ general anesthesia have modified the first, but most experts using air have become reconciled to a three to five day recovery period. Dr. Newman brings new hope that, in the use of

ethylene, this purpose may be achieved. Scarff's results, combining the oxygen with tribrom-ethanol anesthesia, compare favorably with Dr. Newman's. While the advantages of rapid absorption of ethylene are obvious, I can see one disadvantage not mentioned by Dr. Newman. This would be the voiding of the important therapeutic application of encephalography. I consider the introduction of a rapidly absorbable gas a distinct contribution to encephalography and a further step in its simplicity.

DR. J. GRAFTON LOVE, Rochester, Minn.: I am in favor of any improvement in the technic of encephalography which will make the patient more comfortable after a procedure that is ordinarily quite painful. There is only one question I should like to ask Dr. Newman. Occasionally it has been necessary to proceed immediately with craniotomy after completing encephalography, because of the patient's condition. This condition has arisen rarely, and it has arisen in patients who have a relatively large tumor which could not be diagnosed otherwise. If we proceed immediately with craniotomy, with ethylene in the ventricular system, I am afraid we shall get into difficulty with the electrosurgical unit because of the explosive substance used.

DR. TEMPLE FAY, Philadelphia: At Temple University we have worried over the problem of preparation of the patient and the relief of headache which the patient suffers after encephalography since 1926. In our series we have had more than 700 cases. From our standpoint and the roentgenologist's standpoint we have found that to give the patient ether spoils the true definition of the cortical pathways, as apparently ether causes a rapid obliteration of the cortical pathways by swelling of the brain. We use tribrom-ethanol with a great deal of satisfaction. We have not tried ethylene. We prepare our patients twenty-four hours before the encephalogram. We administer bromide and chloral the morning of the encephalogram and during the period following the taking of the encephalogram. We have been more and more impressed during the last three years that the matter of headache and reaction is determined chiefly by the volume displaced. As Dr. Newman has stated, a rapid absorption of the ethylene simply means a more rapid replacement of volume of blood or spinal fluid in the system formerly occupied by air. We have found that the headache phenomenon is due to hyperemic stretch of the blood vessels as spinal fluid volume is withdrawn. Within the cranial cavity, the pain fibers are on the vascular tree, and the stretch mechanism can be produced in two ways: First, by withdrawing spinal fluid and allowing hyperemia or stretch of the large vessels and sinuses (diameter stretch). This headache can be immediately relieved during the encephalography, if one will introduce volumes in excess of what has been withdrawn; in other words, push out the excess blood. Second, by overdilatation of the ventricular-subarachnoid system, in which the arch of the brain stretches the vascular tree and network as the ventricles become distended and again give this pain reaction. We have given up the direct method of ventriculography in favor of the serial method when pressure is high. That is, we introduce a cannula into the ventricle, plugged with cotton, allowing spinal fluid to leak slowly out for the next six to eight hours. The tampon then is removed, and the patient is allowed to produce a spontaneous ventriculogram from the ordinary movements of the head, air being bubbled into the needle as fluid drains out, into sterile dressings. These patients show a minimum reaction of elevated temperature, headache and discomfort. We believe we have gotten away from the dangers of sudden withdrawal of spinal fluid and sudden inrush of blood to take its place. Dr. Newman's paper interestingly enough suggested that within six hours the 100 cc. of ethylene is replaced by either blood or spinal fluid, or both.

DR. HENRY W. NEWMAN, San Francisco: Dr. Keegan's suggestion that ethylene be used in ventriculography is interesting. Since I am purely a neurologist, not a neurosurgeon, opportunity for that at Stanford has not been very great. The objection which Dr. Love raised to its use in encephalography, when immediate operation might be contemplated, certainly must be borne in mind, because I would dislike to have to report the first case of an intracerebral explosion. It is not only possible

Opinions differ as to the mechanisms involved in the production of the typical syndrome of chronic gallbladder disease. Bile stasis appears to be one of the chief physiologic manifestations of inflammatory changes in the gallbladder mucosa. German clinicians especially emphasize stasis of bile as the causative factor producing the characteristic symptoms in the absence of mechanical obstruction due to the presence of stones. The recent and extensive work of Andrews and Henry<sup>6</sup> on the bacteriology of normal and diseased gallbladders supports the stagnation hypothesis. These investigators suggest that bacteria may play but a secondary rôle in gallbladder disease and that more careful study be given to the possible primary factors, which might be mechanical, vascular, toxic or chemical.

Stasis has been attributed to a variety of causes. It is believed that an inflammatory process may result in the stagnation of bile in the gallbladder or biliary passages. These changes may vary from simple catarrhal inflammation to active infection with specific organisms. Mechanical irritation due to the presence of stones may give rise to all types of inflammation of the gallbladder wall. Metabolic disturbances may produce alterations in the physical and chemical properties of bile, impeding its free flow. The sedentary life and the asthenic habitus have been considered by some as etiologic causes of muscular atonia of the gallbladder wall which impairs normal emptying.

Objectively, roentgenologic examination comprises the chief method of studying the gallbladder. There are three possible factors in general, exclusive of failures in roentgen technic, which may account for nonvisualization: (1) failure of the gallbladder to concentrate the dye, because of a pathologic condition of the wall; (2) failure of the dye to reach the gallbladder, because of obstruction of the cystic duct with calculi, and (3) the concomitant pathologic condition of the liver, resulting in the deficient secretion of bile. Regardless of which factor may be considered primary, stasis of bile would be the inevitable result.

From all available evidence, therefore, the rationale of treatment of chronic gallbladder disease should consist in eliminating bile stasis. Certainly little is accomplished toward this end by continuing the use of the almost traditionally accepted low fat dietary and cathartic management. It logically follows that, in the absence of acute mechanical obstruction or acute inflammation, a treatment designed to increase the flow of bile would mediate at least one of the causes of the difficulty.

In 1924 one of us (C. F. G. B.) began giving cream, butter and in some instances eggs, plus a diet of frequent feedings of high smooth bulk, together with antispasmodics, to patients with low grade gallbladder disease. Cooked fats or so-called greases were absolutely curtailed. The results proved satisfactory and the policy was continued. The patients who responded best were those who had previously been on the restricted unbalanced diet considered correct for gallbladder disease. Those who continued to show more severe symptoms and signs were sent to the surgical department in good general condition.

During this preliminary study, many bile salts with or without cathartics were used on control patients. These either became worse clinically than the patients given the diet plus antispasmodics or remained unchanged until we began using keto-cholanic acids three years

ago. The use of keto-cholanic acids as an adjunct to our previous dietary management was suggested by K. K. Jones<sup>7</sup> on the basis of its action in stimulating a flow of hepatic bile.

The choleric effect<sup>8</sup> of the bile acids is now well established. Thus far, however, their usage has been confined chiefly to the laboratory, and little attempt has been made, to utilize them clinically. On the basis of their physiologic activity, various forms of bile salts have been used by Copher, Woodmansee and Moore,<sup>9</sup> Whitaker<sup>10</sup> and others in an attempt to accelerate the appearance of the gallbladder shadow in cholecystography. Graham, Copher and Moore<sup>11</sup> conclude that bile salts are not satisfactory for this purpose. More recent work by Jankelson and Altman<sup>12</sup> would indicate that the matter is still an open issue.

Of the various cholic acid derivatives employed both experimentally and clinically, the keto-cholanic acids, the oxidation products of the natural bile acids, have been shown to have the lowest toxicity.<sup>13</sup> They are apparently the only bile salt preparations that may be administered intravenously in man. The increase in the flow of liver bile following the use of this substance is claimed to be from 100 to 200 per cent.<sup>14</sup> In determining the relative toxicity of different bile salts on the gallbladder of the normal dog, Andrews and Aronsohn found that the most severe reactions resulted from the use of desoxycholic acid. Taurocholic acid, apocholic and cholic acid, and hydrolyzed bile salts produced less marked but severely toxic reactions.

We believe that the use of keto-cholanic acids in conjunction with a frequent feeding, high fat, dietary regimen achieves a twofold action. First, the direct stimulation to the flow of liver bile as obtained by the administration of keto-cholanic acids results in the increased activity of the entire biliary apparatus as well as the gallbladder. Second, the physiologic action of fat in initiating contraction and emptying of the gallbladder is obtained. Theoretically, the resulting increased flow of bile through the gallbladder should exert a mechanical flushing action and result in drainage of the biliary tract.

#### METHODS AND MATERIAL

Patients were selected for this study who had been observed and treated for upper abdominal distress for varying periods of time. All of this group underwent routine cholecystographic examination and those who showed dysfunction were accepted for the series. New patients entering the clinic during the study with symptoms referable to the gallbladder were similarly treated. In addition to the foregoing group of patients, who were seen in the gastro-intestinal clinic of St. Luke's Hos-

7. Jones, K. K.: Personal communication to the authors, January 1933.

8. Both Graham and Rehfuess and their co-workers distinguish between choleric and chologogues. The former term includes those substances, chiefly the bile acids, which increase the flow of bile by directly stimulating the liver to secrete more bile. The chologogues are those substances which increase the flow of bile by inducing emptying of the gallbladder.

The fourth form of chronic gastritis, that of the postoperative stomach, offers the worst prognosis. All three forms of gastritis occur combined (fig. 5).

The general practitioner wishes to be able to make such an important diagnosis without the aid of complicated methods. Therefore we carefully surveyed 228 cases of gastritis seen at the University of Chicago. We selected fifty-three cases that showed the most marked and undeniable gastroscopic picture not combined with any other disease.

Fig. 2.—Superficial gastritis: A, gastroscopic picture reveals thick purulent secretion. B, microscopic section shows advanced cellular infiltration only of the upper layers of the mucosa.

The ages of the patients ranged from 20 to 60 years. Our statistics contradict Henning's statement that the gastritis anamnesis is a short one. The average dura-

Small folds.....	1. Normal mucosa 2. Atrophic gastritis

tion of symptoms in our cases was five and one-half years. Hypertrophic gastritis predominated in the male, and the other forms were equally distributed. The subjective symptoms varied. Appetite was often poor but sometimes was normal. The distress was usually epigastric; in the superficial and hypertrophic form it was usually delayed; in the atrophic form it appeared from one to thirty minutes after meals. The site of the lesion (antrum or body) was of no importance. Periodicity seemed to be present in some cases of hypertrophic gastritis, but this was not as marked as in ulcer histories. Alkali gave relief in about half of the cases, but only in the superficial and hypertrophic form. Aggravation by large amounts of food or by special foods was infrequently found. Many complained of gas and belching. In all forms the intestinal function was normal.

Physical examination was usually negative. At times upper abdominal tenderness was present. One of us (R. S.) has described a tender zone (fig. 6) below and to the left of the navel, which is found only by very light palpation made slowly from the left iliac crest toward the navel. This is by far the most reliable physical sign of chronic gastritis. Gastric analysis, acidity tests, other chemical tests and the cell count of the stomach content are almost useless. All gastroscopists thought that there was an achlorhydria even in the

mildest forms of atrophic gastritis. However, we can show that free hydrochloric acid is often present. In one case of complete atrophy of the body plus superficial gastritis of the antrum we found marked hyperacidity. Increase of mucus may be found in a few cases of superficial gastritis. A marked positive urobilinogen reaction in the urine points toward a concomitant duodenitis.

X-ray relief technic, which gives such splendid results in ulcer and cancer diagnosis, is disappointing in chronic gastritis. Since Berg, the outstanding proponent of the method, has admitted this, we may omit our experiences. The accompanying table by Henning<sup>5</sup> shows well the relation between the folds of the x-ray relief technic and the gastroscopic picture. However, in cases in which polyp-like inflammatory nodes are formed, the so-called granulation relief is found. Unfortunately we have seen it in only one of 200 cases of chronic gastritis.

Gastrophotography is of little value. The best panchromatic films are not sensitive enough for this part of the spectrum.

Since there is no absolute clinical symptomatology in chronic gastritis, only gastroscopy can confirm or rule out this important disease.

#### TREATMENT

The suffering of the patient and the dangers and sequelae of chronic gastritis make careful treatment imperative. In all gastritis the therapy must consist of a bland diet in frequent, small amounts. Raw fruits and vegetables are absolutely contraindicated. For effective treatment the type of gastritis and the immediate form must be considered. In the superficial type in which it is very important to avoid the development of the atrophic form, bed rest of at least eight days and hot applications are necessary. If pus or other secretions are abundant, regular lavages are almost indispensable. In hypertrophic gastritis lifelong strict diet is necessary. If erosions are present they may be irrigated, as Henning suggests, with weak silver solution. In atrophic gastritis milk must be completely avoided. Hydrochloric acid relieves the sensation of pressure and the disagreeable taste. Parenteral liver therapy may be tried in all atrophic forms.

Fig. 3.—Atrophic gastritis: A, gastroscopic picture suggests thinning of mucosa, greenish gray and prominent submucosal vessels. B, microscopic section shows thinning of mucosa, absence of glands, and metaplasia. Development of goblet cells.

We shall briefly mention some important problems of chronic gastritis:

1. Gross, sometimes fatal, hemorrhages from gastritis have occurred. Perforation has not been seen.
2. Superficial gastritis is not always harmless. One of us (R. S.) observed a case in which it was followed by secondary ascending cholangitis and death.

5. Henning, N.: Ueber die Entzündung des Magens, Deutsche med. Wchnschr. 60: 1455 (Sept. 28) 1934.

quadrant, distention and the like. These symptoms subsided after changing to the bland diet. In two patients, typical attacks of colic resulted. One of these patients who was under observation at the University of Illinois reported an attack of colic two days after the combined keto-cholanic acid and hourly feeding therapy was begun. The attack was followed by a slight diarrhea, during which the patient felt some granular material in the stool. Some of the granules, varying from 2 to 4 mm. in diameter, were recovered by the patient and brought to the clinic. Examination by the pathology laboratory revealed these to be typical faceted cholesterol stones.

#### COMMENT

While we have employed cholecystography as the chief objective criterion of improvement in this investigation, we realize its limitations. The problems of roentgen interpretation and methods are almost as controversial as the status of cholecystitis. There is little doubt, however, that cholecystography is the best objective method of study that is available.<sup>16</sup>

The need for care in interpreting roentgen improvement was indicated by the work of Lahey and Jordan.<sup>17</sup> They found that in 44 per cent of a series of sixty-five cases of cholecystitis, also manifesting signs of colon irritability, the gallbladder would fill normally after from five to ten days of bowel management, whereas with the same intravenous dye technic it had previously shown an absence or an inadequate filling.

No conclusions can be drawn at this time as to the proper interpretation of the roentgen improvement in the visualization of the gallbladders of the patients receiving the keto-cholanic acids. The roentgen changes may be the result of an actual increased activity of the gallbladder due to improvement in the pathologic gallbladder wall. On the other hand, since the liver cells are directly stimulated to secrete, more bile passes through the biliary apparatus, probably because of improved mechanical flow resulting from the increased amount of bile from the liver itself. The consistent improvement manifested by the keto-cholanic acid series and the lack of improvement in the control series must be considered significant.

Regardless of the objective signs of improvement, various aspects of which are controversial, the consistent subjective improvement remains quite definite. The patients almost uniformly obtained relief not attainable on principles of gallbladder management previously laid down. Relief from "dyspeptic" distress, cessation of colic, weight gains and the like were striking.

Care must be exerted, however, in selecting patients and in carrying out the combined keto-cholanic acid and high fat dietary therapy. This form of management is distinctly contraindicated in cases of either common duct obstruction or acute cholecystitis. We recommend the gradual introduction of the management rather than beginning all measures abruptly. If, for example, a patient has been maintained on a low fat, low cholesterol dietary regimen, the same diet should be continued and the keto-cholanic acids ( $3\frac{3}{4}$  grains three times a day, after eating) begun. As the patient responds, the diet is gradually liberalized, being changed to a bland general diet and ultimately to the hourly feedings of milk and cream.

Failure to improve clinically, as manifested by continued pain, jaundice and repeated colic, after a reasonable trial period of the foregoing management definitely indicates surgical intervention. Although we have included all forms of pathologic changes termed chronic cholecystitis in this series, we have not as yet referred a single case to surgery.

#### CONCLUSIONS

We find no justification in continuing the use of low fat, low cholesterol dietary management in the treatment of low grade gallbladder disease except in a few special cases. We recommend keto-cholanic acids to stimulate the flow of hepatic bile, hourly feedings of milk and cream to stimulate emptying of the gallbladder, and antispasmodic medication. This was found to be the most effective type of therapy in our series from the standpoint of objective and subjective improvement in cases of chronic cholecystitis. We believe that this form of therapy is distinctly contraindicated in cases of common duct obstruction and acute cholecystitis.

## ENCEPHALOGRAPHY WITH ETHYLENE

HENRY NEWMAN, M.D.

SAN FRANCISCO

The very considerable discomfort following encephalography by the lumbar route has been a potent factor in limiting the application of this diagnostic procedure. One can look for the most help from encephalography in those cases in which a suspicion rather than a certainty of intracranial disorders exists, yet one is often loath in such cases to subject the patient to the protracted and severe headache which almost invariably follows the procedure. Thus any modification of technic that will serve to lessen the unpleasantness of encephalography will be effective in increasing its scope of usefulness.

General anesthesia, either parenterally or by inhalation,<sup>1</sup> is successful in overcoming the headache incidental to the injection of the air but can have no effect on the pain of the succeeding hours and days. It has the disadvantage of masking the signs of untoward sequelae, thus preventing the prompt institution of necessary therapeutic measures.

Elsberg and Southerland<sup>2</sup> felt that there was a definite connection between the presence of air in the lateral ventricles and the third ventricle and the production of postinjection headache, although they did find a small amount of air persisting in these localities after the headache had disappeared. They believed that increased spinal fluid pressure could be ruled out as an etiologic agent, since they found the pressure to be from 2 to 12 cm. less after the injection than before. Tschugunoff,<sup>3</sup> however, found a definite increase in pressure after encephalography. I have been unable

whether it is his experience, as that of Dr. Faber, that gastritis is the cause of the achlorhydria found in many patients past middle age.

DR. GEORGE B. EUSTERMAN, Rochester, Minn.: I want to pay tribute to Dr. Schindler because of his pioneer work in the development of the modern gastroscope and in gastroscopic diagnosis. His presence here will stimulate us to renewed efforts in this important field. While I agree with Dr. MacCarty's observation that no physician should make an unequivocal diagnosis of gastritis without gastroscopic confirmation, certainly this disease entity is of primary interest to the physician; otherwise neither gastroscopists nor pathologists would have the opportunity of seeing many cases of this nature, except perhaps in those rare instances in which the clinician is also a competent gastroscopist. The present problem of most concern to physicians and surgeons, simply stated, is this: To what extent is gastritis or gastro-enteritis, especially in its chronic form, the underlying cause in those conditions frequently diagnosed as pseudo-ulcer, nervous indigestion, gastrototoxic hemorrhage, duodenitis, gastrogenic diarrhea, achylia gastrica, pseudocholecystitis and those relatively infrequent cases presenting antral defects, usually labeled scirrhus carcinoma or syphilis but without evidence of either on histologic examination of the resected tissue? The same problem applies to certain late postoperative sequelae. Certain primary and secondary types of gastritis, acute, subacute, chronic, phlegmonous, specific and perianastomotic, have long been familiar, and more is being learned each day

Fig. 6.—Zone of tenderness, sometimes elicited with chronic gastritis.

about the nature and extent of gastritis in association with ulcer and cancer, especially from the histologic standpoint, as it is seen here in America. I recently reported a series of ten primary forms of subacute and chronic gastritis in which the inflammatory process was sufficiently extensive to give rise to gross defects, usually antral in situation, and recognizable by the ordinary roentgenologic technic. Such defects were indistinguishable from those produced by carcinoma in particular, by syphilis, by chronic hypertrophy of the pylorus, and by gastric ulcer when associated with antral spasm. From a symptomatic standpoint the cases could be roughly divided into three types according to whether they simulated (1) cases of ulcer or cancer with irregular symptomatology, (2) cases in which the symptoms closely simulated those of ulcer, and (3) cases characterized by pain or simulating biliary colic. The question naturally arises as to how often gastric disturbances are due to patchy or diffuse inflammatory states unrecognized or misinterpreted in the absence of roentgenographic appearances and routine gastroscopic study.

DR. RUDOLF SCHINDLER, Chicago: I was glad to hear that Dr. MacCarty takes such a view of the clinician's conception of the chronic gastritis. I am afraid the work of clinicians is based on the lack of a clear definition of the normal histologic picture of the stomach of the adult, and I want to emphasize the danger of the clinical diagnosis of gastritis without gastroscopy. It is now such a common diagnosis that one can be quite sure that it is often a wrong diagnosis. That refers especially to the x-ray diagnosis. Because 50 per cent of all people with epigastric distress suffer from chronic gastritis, one would be correct in 50 per cent of all cases to "guess" the diagnosis of chronic gastritis. Therefore, on the law of averages, the roentgenologist should be correct in one half of his cases with epigastric distress, but the x-ray diagnosis is still only a "guess." The question Dr. Bloch asked about anacidity in gastritis can be answered easily. There are many cases of anacidity without gastritis and many cases with gastritis. This differentiation can be made only by the gastroscope.

## Clinical Notes, Suggestions and New Instruments

### DISLOCATION OF CERVICAL VERTEBRAE: OPERATIVE CORRECTION

EDWIN W. RYERSON, M.D.

Senior Attending Orthopedic Surgeon, St. Luke's Hospital  
CHICAGO

AND

FREDERICK CHRISTOPHER, M.D.

Associate Professor of Surgery, Northwestern University Medical  
School; Chief Surgeon, Evanston (Ill.) Hospital  
EVANSTON, ILL.

G. E. T., a man, aged 43, was admitted to the Evanston Hospital on Sept. 9, 1934, immediately after he had been thrown from a horse, striking directly on the left occipitoparietal region of his head. X-ray examination at this time showed no fracture of the cervical spine, but a slight forward dislocation of the sixth cervical vertebra on the seventh. The dislocation was readily reduced by placing the neck in extension and exerting from 3 to 4 pounds of traction on the head. He was discharged from the hospital September 20, wearing an aluminum neck-brace, which supported the head and held the neck in extension. Reexamination of the neck by x-rays three weeks later showed that the luxation had recurred and had even increased, and the patient was having considerable pain in the neck at this time. He was readmitted to the hospital October 18. Traction was applied to the head and hyperextension of the neck was obtained by placing the patient's body on two mattresses and allowing the head to hang over the edge. November 13 he was again gotten up with the neck-brace and the dislocation immediately recurred (fig. 1A). Operative correction was now decided on and three types of operations were considered: first, the bone graft; second, spinal fusion, and, third, the wiring together of the spinous processes, which had been suggested to Dr. Christopher sometime previously by Dr. Reginald H. Jackson of Madison, Wis. Dr. Ryerson saw the patient in consultation and concurred in this advice. Operation was done by Dr. Christopher November 17. The patient was anesthetized

Fig. 1.—Operative correction of dislocation of cervical vertebrae: A, dislocation of sixth cervical vertebra on the seventh; B, restoration of contour following the wiring together of the spinous processes of the sixth and seventh cervical vertebrae.

with ether and placed in the prone position. The muscles were separated from the spinous processes, and the sixth and seventh spinous processes were identified. By means of Lewin's large towel clip, holes were made in the spinous processes. In the sixth the hole was in the anterior portion, and in the seventh in the posterior portion. Strong iron "stove-pipe" wire was then passed through the holes, crossed over the posterior portion of the spinous process of the sixth cervical vertebra and (fig. 1B) tightened up with the neck extended.

able to judge the degree of discomfort of these human subjects more accurately than would have been the case with semianesthetized dogs. I must therefore state that I cannot, in man, confirm Aird's finding of definite anesthesia or analgesia produced by injection of ethylene.

After the injection, however, the condition of the patient presented a striking contrast to that seen after

Fig. 2.—Encephalogram after removal of 100 cc. of spinal fluid and replacement with approximately 150 cc. of ethylene.

the use of air. Most of the patients were quite comfortable within three or four hours, able to eat the evening meal, and in almost every instance to be up and about the following day. The average period of hospitalization following the procedure was reduced from three days when air was used to 1.85 days with ethylene, while the condition of the patients on dismissal was in general better than after the longer period with air. That this shorter period of recovery from headache is due to the more rapid absorption of ethylene seems most probable. I believe that the solubility of the gas, and not its anesthetic properties, is responsible for its advantage over air.

It is generally stated that although air in the subarachnoid space may be absorbed within twenty-four hours<sup>8</sup> ventricular air is present at least three days<sup>9</sup> and may at times be seen nine days<sup>8</sup> after the injection. I have seen a case in which twenty-one days after the injection of a large volume of air it could still be observed in the ventricular system.

Serial x-ray studies after the injection of ethylene showed the subarachnoid gas to disappear within a very short time. Although the ventricular gas was half gone within three hours, some small residue could be seen even twenty-four hours later. It is well known that any collection of gas in the body tends to come into equilibrium with the tissue gases,<sup>10</sup> so that the gas remaining this long after injection was probably composed more of nitrogen and oxygen than of ethylene.

In two cases, lumbar puncture the day after the injection showed cell counts of 1,200 and 1,400 leuko-

cytes, comparable to similar counts after air,<sup>9</sup> which would indicate that ethylene possesses no more irritating qualities than does air.

The ready solubility of ethylene raised the possibility of its being absorbed more rapidly than fluid could be formed to take its place, with resulting production of a negative cerebrospinal fluid pressure. To investigate this point, a patient was subjected to encephalography, but one needle being used to minimize leakage, and the pressure during the injection and for five hours thereafter was recorded by an aneroid manometer capable of registering both positive and negative pressures, the lumbar puncture needle being undisturbed during this time. The curve of spinal fluid pressure against time so obtained is seen in figure 3. Since during the injection the patient was sitting up, and after it he was lying down, the pressure readings, while the patient is in the sitting position, are corrected by the subtraction of 20 cm. to make them comparable to those while the patient is recumbent. Thus it is observed that the pressure dropped sharply after injection and at the end of an hour reached a negative value of 13 cm. of water. At two hours it had attained zero and subsequently rose to normal values. That such a marked change in pressure may be undesirable from the standpoint of the safety of the patient must certainly be borne in mind. I can only say that in a series of thirty-eight cases it has not been productive of serious sequelae. Nor can this freedom from untoward consequences be accounted for by selection of cases, as the wide variety of diseases in which the gas was used is evident from inspection of table 2.

A disadvantage of the use of any absorbable gas for diagnostic encephalography is the elimination of the examination on the second day, which is of value in certain cases.<sup>11</sup>

Whether encephalography with ethylene will be productive of the same therapeutic results claimed for the procedure with air, notably in post-traumatic headache, remains to be seen.

Fig. 3.—Spinal fluid pressure during and after encephalography with ethylene.

#### SUMMARY

Encephalography with ethylene has been done in thirty cases, without mortality or serious sequelae and with radiologic results equal to those obtained with air. Although the discomfort of the period of injection is not noticeably lessened, the severity and duration of the postinjection headache is markedly reduced. This advantage of ethylene over air warrants its clinical trial in a larger series of cases.

The operation was done a number of times by Chipault.<sup>4</sup> Church and Eisendrath<sup>5</sup> refer to a case in which "the two spinous processes were connected by means of a very large silk ligature." In 1898 Brokaw<sup>6</sup> reported a case of fracture-dislocation of the seventh cervical vertebra in which "the segments of vertebrae were wired, and pressure and symptoms relieved." Reference to the operation is also made by Constantinesco,<sup>7</sup> Lloyd,<sup>8</sup> Speed<sup>9</sup> and Mixter and Osgood.<sup>10</sup>

### FRACTURED RIBS WITH PARADOXICAL MOTION

JOSEPH B. STENBUCK, M.D., NEW YORK

It is important in treating a patient with fractured ribs to place the least emphasis on the broken bones. If attention is focussed on the ribs, certain other more important associated injuries may be overlooked. It is wise to think of all cases of fractured ribs as possible cases of subcutaneous or concealed penetration of the chest. That is, a piece of rib at the fracture site may be as pointed and sharp as a knife and may produce any of the complications of penetrating wounds of the chest. The most important of these are pneumothorax, hemothorax and subcutaneous emphysema. These conditions may produce symptoms and death sometimes erroneously attributed to contusion of the chest with shock and collapse and should be looked for in every case of fractured ribs and corrected when necessary. Aspiration of intrapleural air, and of blood when symptoms of pressure occur, is essential. The pneumothorax apparatus in recording intrapleural pressure and in removing air when necessary is indispensable.

Strapping of the chest with adhesive plaster is an almost universal but questionable procedure. It produces some immo-

may be realized. It may be better to reserve strapping for the type of case described herewith and to depend on medication for relief of pain in the other cases.

To the list of complications of fractured ribs I add another one, the significance of which I have not seen described. It is illustrated by the case of C. I., a man aged 36, admitted to the Harlem Hospital, June 21, 1936, following an automobile accident. There were many abrasions and lacerations but the

Fig. 2.—In expiration: The plaque bulges outward while the rest of the chest collapses as in normal expiration. The mediastinal structures then move to the injured side. The motion of a portion of the thoracic cage in a direction opposite to the normal is known as paradoxical motion, and its bad effect on the normally stable mediastinum is illustrated in this case. A condition of mediastinal flutter is produced resulting in cardiovascular and respiratory embarrassment. In the diagrams only a small portion of two ribs is shown. It is possible, of course, for the condition to exist involving many ribs and larger portions of ribs.

Fig. 1.—In inspiration: The plaque consisting of portions of two adjacent ribs together with the corresponding soft tissues of the chest wall are drawn inward, while the rest of the chest wall expands as in normal inspiration. This allows the mediastinum (represented diagrammatically by the trachea but including of course the heart and great vessels) to be drawn toward the opposite side of the chest.

bilization of the chest and decreases pulmonary ventilation. Since most fractures of the ribs occur in elderly persons who are prone to pulmonary infection, the importance of this factor

important injuries were multiple fractured ribs in the right side of the chest and a compound fracture of the right leg, which was amputated because of gas bacillus infection.

In the right side of the chest there was found a small area of subcutaneous emphysema and an extensive hemopneumothorax. (Later the blood became infected, requiring drainage.) In addition, in the anterolateral portion of the right side of the chest it was noted that in an area roughly 12 cm. in diameter the chest wall expanded with expiration and collapsed with inspiration in contrast to the rest of the thorax, which expanded with inspiration and collapsed with expiration in the normal manner. Palpation revealed double fractures of two adjacent ribs as indicated in the accompanying illustrations. This plaque of chest wall had lost its firm bony support and moved freely with respiration.

This phenomenon of paradoxical motion is commonly observed after extrapleural removal of ribs in thoracoplasty. In this case, although the ribs were not removed, the effect was similar in releasing a portion of the normal support of the lung. The patient was very dyspneic. This might have been due to the hemopneumothorax. However, when the chest was firmly strapped with adhesive plaster the marked dyspnea disappeared immediately. Strapping was employed for twelve days, after which it was noted that the paradoxical motion had ceased.

### SUMMARY

Cases of fractured ribs should be considered in the light of the abnormal physiologic changes or complications that may occur rather than as cases of broken bones. The most important complications are pneumothorax, hemothorax and subcutaneous emphysema. The case reported demonstrates a complication of paradoxical motion with apparent disturbance of the mediastinal vascular structures. This complication involving the mediastinum has not, to my knowledge, been previously described.

but probable that such proportions of ethylene and air, which would be explosive in nature, might well be present even as long as twelve hours after encephalography. I do not think that the types of gas which might be useful in this procedure have by any means been exhausted. The only feature that is of importance is the solubility of the gas and its lack of toxic properties. I am sure that chemists will be able to supply a gas which is as soluble as ethylene but which doesn't blow up when the radio knife is used near it. The volume for volume replacement method obviously cannot be used with ethylene, since, as I said, there is a considerable amount of the gas absorbed during the injection. Therefore it is quite possible that it is not possible to preserve volume relationships as well, and the fact that there is less headache with ethylene, in spite of that, makes me even more enthusiastic for the gas. That the gas is actually of considerable value in reducing the second type of headache, that which may well occur from the presence of gas in the brain cavities, is well borne out by our patients, who present a marked contrast to the usual very sick patients that I have encountered when air was used. I feel I am conservative in stating that it has a definite advantage in the comfort of the patient following the procedure and none whatever in the comfort of the patient during the procedure, for they are just as sick as they are with air.

## CHRONIC GASTRITIS

CHICAGO

The diagnosis of chronic, nonspecific gastritis has been obsolete for thirty years. Recent histologic and gastroscopic research have shown that chronic inflammation of the stomach is very common.

Bensley, Faber,<sup>1</sup> Konjetzny<sup>2</sup> and others have made extensive contributions to the knowledge of the histology of the stomach. However, the normal histologic picture is still debatable. Specimens from healthy normal stomachs are rarely obtained because postmortem changes alter the picture, and healthy stomachs are not resected. Some workers, comparing the mucosa of infants to that of adults, believe that every adult has chronic gastritis. This is as false as saying that every adult has chronic appendicitis because microscopically there is a round cell infiltration. We believe that these minor histologic changes in the stomach are not evidence of active disease but are the normal reaction of the stomach to such stimuli as hot or cold food, infectious diseases, and the like. Such changes should not be considered a pathologic entity. It is not chronic gastritis. Severe chronic inflammation is well seen microscopically in postmortem specimens injected immediately with solution of formaldehyde, but the interpretation of surgically resected specimens is doubtful.

Clinical chronic gastritis was rediscovered with gastroscopy by the senior author in 1922.<sup>3</sup> Since then European workers have built up a voluminous literature on the subject. In contrast to histologic study, gastro-

copy can be carried out in healthy persons as often as necessary. This has been done systematically in persons of all ages. We found the normal mucosa to be smooth, silk-like, glistening and orange red. Figure 1 shows this gastroscopic picture and a microscopic section through the most normal portion of the mucous membrane that we could find. It shows the surface epithelium, the long body glands, and the scant interstitial tissue, which is almost free of cells.

We have examined more than 2,500 patients gastroscopically, all of whom had abdominal complaints. Twenty-three per cent of this group had normal stomachs gastroscopically, as judged by the appearance of stomachs in healthy persons without evidence of any disease. About 50 per cent of this group presented mucosal changes similar to those of chronic inflammation of other mucous membranes. We saw either layers of whitish, grayish or greenish mucus or hyperemic spots similar to those observed by Beaumont 100 years ago (fig. 2). We observed that these stomachs usually healed. This picture was designated "superficial gastritis." Microscopically the cells show cloudy swelling and slight interstitial infiltration.

Some cases in this group, however, showed in later gastroscopic examinations another picture: thin greenish gray spots appeared that did not change in subsequent examinations. An "atrophic gastritis" had developed. Atrophic gastritis has been observed without a preceding superficial gastritis, for instance, in cases of pernicious anemia. Total atrophy has been observed also. The whole mucous membrane was thin and greenish gray, and protruding blood vessels were seen (fig. 3). Chester Jones and Benedict<sup>4</sup> have shown that regeneration of the mucosa is possible in cases of pernicious anemia, and we have made the same observation. Microscopically the glands are rarefied, and the mucosa is thinned. We are indebted to Dr. James B. Carey of Minneapolis for the photomicrograph of atrophy in pernicious anemia.

The third form is the "hypertrophic gastritis." It is a separate clinical entity. Gastroscopically a swollen, thickened, velvety mucous membrane is seen, often con-

Fig. 1.—Normal stomach: A, gastroscopic picture reveals smooth glistening mucosa of antrum and lesser curvature of body. B, microscopic section through a fold consisting of mucosa, muscularis mucosae and submucosa with slight but definite interstitial cellular infiltration, which cannot be considered pathologic.

taining hemorrhages and erosions (fig. 4), often showing nodules or large nodes, creases and crevasses. The course of hypertrophic gastritis is typified by failure of the mucosa to revert to normal and sudden recurrence of symptoms even while on careful management. We observed some of these cases over many years (one patient was examined gastroscopically sixty-five times). The small erosions always heal within a week, but others may appear concurrently. No atrophy develops.

antidotes generally listed are atropine, caffeine, strychnine, camphor, cocaine, apomorphine and lobeline; but none are more than partially effective. Their value is merely accessory to treatment by repeated washing of the stomach—morphine is excreted from the blood into the stomach—plus inhalation of carbon dioxide and oxygen.

Such are the main facts and considerations with regard to the respiratory stimulants that may be administered by mouth or by subcutaneous or intravenous injection. Their importance tends to decrease in proportion as experience increasingly demonstrates the superiority of the inhalational drug that nature offers as the normal respiratory stimulant: carbon dioxide.

#### THERAPEUTIC USE OF THE RESPIRATORY GASES

Until quite recent years the general conception of the therapeutic values of oxygen and carbon dioxide were largely erroneous, and these errors still linger in textbooks.<sup>5</sup> Because a fire burns more vigorously when supplied with a higher percentage of oxygen instead of air, it was supposed that the life processes of the body must be affected similarly. In fact, on the contrary, as we now know, a normal man breathes no more vigorously and consumes no more oxygen when breathing 100 per cent oxygen than when breathing ordinary air containing only 21 per cent. Oxygen is a food, the most immediately necessary of all foods; but it is not a stimulant. After asphyxia it may even act as a respiratory depressant.

Carbon dioxide was even more completely misunderstood. It was regarded as *par excellence* the asphyxiant gas, and to have administered an inhalation containing carbon dioxide would a few years ago have been condemned as obvious malpractice. It is now known that, on the contrary, the carbon dioxide produced in the body is normally the factor that controls and stimulates respiration. When respiration has been depressed, carbon dioxide by inhalation is a most effective stimulant. It must indeed be diluted to something like physiologic concentration either with air or with oxygen. But in all such mixtures the drug that affords stimulation to respiration and the circulation is carbon dioxide; the oxygen and air are essentially diluents.

The common statement regarding carbon dioxide is that it increases the volume of breathing. In fact, however, this is only one of its effects; another of equal importance is the increased tonus that stimulation of the respiratory center by carbon dioxide induces in the thoracic muscles and diaphragm, and to some degree in all the muscles of the body. It is the tonus of the respiratory muscles that normally keeps the thorax and lungs expanded and prevents atelectasis. It is the tonus of all the muscles of the body, skeletal and visceral, that normally presses the blood on into the veins and maintains the venous return to the right side of the heart, which is a prime factor in maintaining the circulation. It is the lowered tonus of the body as a whole, rather than that of the vasomotor system, which underlies all the depressions of function after surgical operations and in acute illness, and particularly pulmonary complications and failure of the circulation.<sup>6</sup>

The first use to which inhalation of carbon dioxide was put was that of controlling respiration under anes-

thesia. Before carbon dioxide was introduced for this purpose, the combined effects of overbreathing during the excitement stage of anesthesia, plus the depression of respiration in deep anesthesia, made apnea a frequent occurrence and fatalities occasional. Preliminary morphine, otherwise advantageous, increased the tendency to early apnea, which is now prevented by means of carbon dioxide. If cyanosis occurred, the condition of anoxia disturbed the respiration of the tissues and induced a decrease of carbon dioxide and a consequent postoperative depression of vitality. Acapnia from all these causes induced a feeble respiration, which prolonged the period of emergence from anesthesia, together with nausea and gas pains. Now, on the contrary, with the aid of carbon dioxide, the competent anesthetist is able to a large extent to avoid these evils and to exert an almost complete control over respiration before, during and after anesthesia.<sup>7</sup>

Until recently, most of the postoperative pulmonary sequelae, such as patchy atelectasis and massive collapse, were supposed to be due to irritation of the lungs by the anesthetic vapor or to insufflation of infective material. The fact that these conditions frequently occur also after spinal anesthesia demonstrates the inadequacy of this explanation. The initial cause of postoperative pulmonary complications is rather to be found in the lowered tonus of the thoracic muscles, and particularly of the diaphragm, under anesthesia and during the period of postoperative depression of vitality. Any considerable decrease of tonus permits deflation of the lungs and accumulation of mucus and closure of some of the airways. A rapid absorption of the air from the occluded areas then completes the development of atelectasis. Inhalation of carbon dioxide, aided by frequent change of position, has proved to be an effective means of inducing an increase of tonus, full inflation of the lungs and the prevention, or relief, of postoperative pulmonary trouble, as well as restoration of a full circulation.<sup>8</sup>

Soon after the establishment of carbon dioxide in connection with anesthesia, the same inhalation was applied for the relief of asphyxia. Analysis of the mode of development of carbon monoxide asphyxia showed that, as soon as the victim becomes seriously short of oxygen, overbreathing develops. Acapnia is thus added to anoxia and induces a continuance of subnormal breathing even after the victim is removed from the poisonous atmosphere. Consequently in cases of severe asphyxia the administration of pure oxygen is quite ineffective as a means of resuscitation, for the gas is not adequately inhaled. The addition of carbon dioxide to the oxygen effectively counteracts this condition. Vigorous breathing is induced, the lungs are dilated and flushed with oxygen, the carbon monoxide is rapidly eliminated from the blood, muscle tonus is increased, the venous return is augmented, and the circulation is thus supported and stimulated. Post-asphyxial illness is diminished and necrotic developments in the nervous system are prevented.<sup>8</sup>

In the asphyxia of the new-born there can, of course, be no previous overbreathing. It was therefore assumed that there could be no acapnia and no ground for the use of carbon dioxide. In fact, however, experience has shown that carbon dioxide is quite as effective—a means of stimulating the respiration of the nonbreath-

3. We do not believe, as do Konjetzny, Hurst and Knud Faber, that gastric ulcer originates from chronic gastritis. A discussion of this question will follow in a later publication.

4. Atrophic gastritis may precede gastric carcinoma, as believed by many pathologists.

5. The relationship between chronic gastritis, pernicious anemia and combined cord degeneration is well known but not fully explained.

Fig. 4.—Hypertrophic gastritis: *A*, gastroscopic picture reveals swelling and nodular appearance in the valleys, erosion surrounded by hemorrhagic area on central fold. *B*, microscopic section shows enlarged lymph nodes with extensive interstitial infiltration throughout entire mucosa. Proliferation of the surface epithelium.

6. Gastritis always threatens the results of gastric surgery. Gastroscopy may teach one how this may be avoided.

7. Perhaps atrophic gastritis may cause very marked psychoneurotic symptoms.

8. True vertigo may be related to gastritis.

9. Moutier finds a relationship between chronic gastritis and dermatoses.

10. Research on etiology is an important problem because little is known.

#### SUMMARY

Chronic gastritis<sup>6</sup> looms as a major problem in internal medicine. It is a very frequent and often a very severe disease. It occurs with many other diseases. The symptomatology is not absolutely characteristic. Physical examination, gastric analysis and roentgenograms are of little aid in making the diagnosis. Gastroscopy with the flexible gastroscope, which is safe and easy and causes little discomfort, is the only method permitting accurate diagnosis. It enables one to treat the patient according to the morphologic indications and possibly to avoid such dangerous consequences as cancer of the stomach.

#### ABSTRACT OF DISCUSSION

DR. WILLIAM CARPENTER MACCARTY, Rochester, Minn.: The solution of any problem rests on definitions which are universally accepted. In this particular subject of gastritis there must be cytologic, histologic, anatomic and clinical criteria before one dares talk about the subject too freely. The only persons who have any right to talk about gastritis are gastroscopists. Possibly an experimental physiologist might have a right to an opinion, but I suspect that clinicians should be careful when they talk. I like to think of acute gastritis as meaning a condition in which there is an edema, which I am sure that Dr. Schindler could see through the gastroscope. No clinician or roentgenologist can see a congestion which Dr.

Schindler can see and which I as a surgical pathologist am able to see; a necrosis, which he and I can see but which the clinician cannot see; a leukocytic infiltration which Dr. Schindler probably cannot see but which I am able to see, and the erosions which he and I can see but which the x-ray man cannot always see. That is what acute gastritis means to me. I think of a chronic gastritis with a lymphocytic infiltration and fibrosis which neither of us can see without a microscope. A hyperplasia or hypertrophy of the mucosa I am sure Dr. Schindler can see. Acute gastritis is not difficult to recognize by Dr. Schindler's method or mine, but chronic gastritis is very difficult sometimes to recognize even by direct visualization. The clinician should be among the last ones to talk about gastritis. I am glad somebody else thinks that cancers of the stomach do not all arise in chronic gastritis. I have never seen an early cancer of the stomach which I thought had its origin in a chronic gastritis, and I have never seen a small cancer of the stomach that didn't arise in association with a chronic ulcer or a polyp. I wouldn't say that cancer never arises in chronic gastritis. That is theoretically possible, and I think maybe Dr. Schindler will see it some day or I shall see it, but as yet I have not seen it. I think it is very dangerous for clinicians to talk too freely about chronic gastritis. If we talk too freely about chronic gastritis, everybody is going to have it, because I think most of us do have it.

DR. LEON BLOCH, Chicago: Dr. Knud Faber's sustained interest in the subject and gastroscopy have restored gastritis to a place as a clinical entity. From personal experience I agree with Dr. Schindler and his co-workers that neither x-rays nor gastrophotography, because of the technical difficulty of obtaining good pictures, are of value in the diagnosis of gastritis. In two of my patients, in whom x-ray examination suggested the possibility of fundal carcinoma, Dr. Schindler was able to disprove the latter diagnosis and demonstrate hypertrophy of the rugae due to gastritis. Many patients with gastritis have no symptoms whatever. Lowered gastric acidity is common in acute infectious disease. Dr. Faber ascribes hypo-acidity and gastroscopically confirmed gastritis to an infectious disease which the patient may have had and forgotten about. While Dr. Schindler can see no relationship between gastritis and ulcer, many European and American investigators are not in accord with him. Gastritis has been found in the resected part of the stomach in almost every case of a large series of patients in whom a subtotal resection was done for peptic ulcer at the

Fig. 5.—Gastritis of postoperative stomach: *A*, gastroscopic picture reveals jejunum visualized (left upper quadrant), erosions on edematous gastric folds, purulent secretion between folds. *B*, microscopic section shows thickening of submucosa with scattered areas of infiltration. Extensive infiltration of the mucosa with erosions partly covered with exudate.

Michael Reese Hospital. I can hardly believe that race or country can have any bearing on gastritis. No doubt the continued use of gastroscopy will ultimately settle the question of the association of ulcer with gastritis. Many patients who have the typical symptoms of ulcer, regularly recurrent postprandial distress, are found to have hyperacidity and no roentgenologic evidences of ulcer. Where resection or a gastro-enterostomy is performed because of the intractable symptoms and refractoriness to treatment, gastritis without ulcer has been found and relief has been obtained. I should like to ask Dr. Schindler

## RESPIRATORY DEPRESSANTS IN LABOR

The most important effect of drugs on respiration occurs in the use—or misuse—of narcotics and hypnotics to ease the pains of labor. In varying degrees all such drugs are respiratory depressants. When administered to the mother they diffuse readily from the maternal to the fetal circulation, and with equal amounts of narcotics in the two bloods the baby is much the more strongly affected. During the early stages of labor this is of no importance. But a dosage that at the time of delivery merely quiets the mother without appreciably depressing her respiration may render the infant so apneic and lethargic that measures of resuscitation are necessary.

The hazard of loss of infant life from the administration of large doses of morphine to the mother late in labor has long been recognized. Morphine decreases the sensitivity of the respiratory center to its normal stimulus, carbon dioxide, in the new-born much more than it does in the adult. I have seen an otherwise normal baby, born of a heavily morphinized mother, that would not breathe at all on any stimulus less than an inhalation of 20 per cent of carbon dioxide, and then too feebly to survive. Less than 2 per cent of all normal babies born of undrugged mothers fail to breathe immediately.<sup>18</sup> But under some of the narcotics and hypnotics now commonly used the percentage of initial nonbreathers rises tenfold or even twenty fold. Under the best hospital conditions the large majority of these infants are successfully resuscitated. Under the less advantageous conditions of outpatient delivery a deeply narcotized baby may never breathe.

In Chicago it was found, in the recent study by the Board of Health,<sup>19</sup> that in more than half the cases in which such drugs as morphine, scopolamine and the barbiturates were used the babies were born in a deeply narcotized condition. In some cases respiration was established with great difficulty. Others died without emerging from their narcotized and asphyxiated state. When only moderate doses were given, the effect on the child was nevertheless that of diminishing his chance of living. The peril to the child was found to be especially grave when large doses of analgesics were given to abolish the pains of labor, followed by administration of solution of posterior pituitary to incite or increase them.

When only moderate doses of morphine are given, and given only in the early stages of labor, the depressant effects of the drug have largely worn off before the baby is required to breathe for itself; and even if the baby is still slightly narcotized, carbon dioxide can generally be relied on to stimulate it to breathe. But the antidotal action of carbon dioxide against the effects of some of the barbiturates is much less effective. For this reason the use of the barbiturates in obstetrics should be confined to those members of this group of drugs the action of which is comparatively brief (two or three hours), and the dosage should be such that the effect of the narcotic is virtually ended (to be replaced by an anesthetic) before the last stages of labor.

The drugs classed as narcotics, analgesics, hypnotics and anesthetics differ widely from one another in three main features. With some, the anesthetic effect is gone

in a few seconds, as with nitrous oxide and ethylene. With others it lasts on for many minutes, as with ether and chloroform. With yet others it passes off in two or three or at most four or five hours, as with codeine and morphine. With still others the narcosis may still be deep after ten or twelve or more hours, and this is particularly the case with some of the barbiturates. Obviously, if the baby is not to be born narcotized, drugs of prolonged effect should be administered only early in labor and only those of brief effect employed in the terminal stages. Even when a drugged baby breathes, it breathes weakly; and its liability to a continuance of atelectatic areas in its lungs and the development of pneumonia is much greater than in the normal child.

The second feature in which these drugs differ is their capacity to induce unconsciousness of acute pain. Some are anesthetics, others merely narcotics. Narcotics and hypnotics should be used early in labor: anesthetics only late in labor.

The third feature that in varying degree renders various drugs suitable or unsuitable for use in labor lies in their influence on respiration. Most of the volatile anesthetics, if administered in moderate amounts, tend to induce some degree of overbreathing and become depressants only when administered in excess. Most of the narcotics, on the contrary, are respiratory depressants even in small dosage and in large dosage bring respiration to a stop. With some of the latter, e. g., morphine, the effects are due merely to a decrease in the sensitivity of the respiratory center to its normal stimulus. If the narcosis is only moderately deep, it may be counteracted by concentrations of carbon dioxide above the normal. With others—notably the barbiturates—the abolition of sensitivity to carbon dioxide is so marked that some investigators who have used these drugs on animals, as well as some obstetricians who have administered them to women, have even been led to doubt whether carbon dioxide really plays a major part in the regulation of breathing. In deep barbiturate narcosis the responsiveness of the respiratory center to its normal stimulus is in fact so nearly abolished that breathing continues mainly under the influence of anoxia. Experiments on animals by Marshall and Rosenfeld<sup>20</sup> have shown that the administration of oxygen by removing this influence may even induce a fatal apnea.

A recent study<sup>18</sup> of various hypnotics in labor led its authors to "believe that morphine or any of its derivatives has no place during labor, as they distinctly delay the initial respirations of the child." On the contrary, the use of considerable dosages of the barbiturates, at least in hospitals, was approved. Yet neither experimental nor clinical evidence seems to justify a belief that for a given degree of protection of the mother from suffering the barbiturates are much less depressant of respiration in the child than is morphine. The safe rule would be that sedatives should not be administered in excess of the amount required to relieve anxiety. The behavior of the infant is the best test of safe practice. Normally its respiration develops as an increase of the respiratory movements of the fetus supported by the development also of sufficient tonus to retain each increment of lung expansion as it is gained.<sup>21</sup> If, on the contrary, any considerable percentage of

The patient made a very satisfactory convalescence and was discharged from the hospital November 28. He wore the neck-brace until December 9. When examined eighteen days later, he had no pain and was in excellent condition.

Jan. 5, 1935, however, he complained of discomfort in the neck. X-ray examination at this time showed (fig. 2a) a fracture of the sixth cervical spinous process, through the drill-hole, with a recurrence of the dislocation.

The patient was readmitted to the Evanston Hospital January 10. On the next day Dr. Ryerson, with Dr. Christopher assisting, performed the following operation: Through a median incision the muscles were carefully separated from the spinous processes and posterior surfaces by the Hibbs subperiosteal dissection, the arches of the vertebrae from the fourth cervical to the second thoracic, inclusive, being completely exposed. The broken off distal fragment of the sixth spinous process and the loop of iron wire were removed.

A new piece of iron "stove-pipe" wire was now passed beneath the arch of the sixth vertebra, between the arch and the spinal cord, emerging in the space between the sixth and the fifth arch. There was plenty of room for this maneuver without any injury to the dura. The upper end of the wire was then bent downward and passed under the base of the spinous process of the seventh vertebra, and the two ends of the wire were twisted together alongside the spinous process

aluminum neck-brace for several months and has since been entirely free from untoward symptoms.

X-ray films made Feb. 28, 1936, more than thirteen months after the fusion operation, show the anterior portion of the body of the sixth vertebra depressed so that it is in contact with the seventh (fig. 4), but the articular surfaces of the lateral joints have become firmly fused in practically normal position. The tibial bone-grafts have also been securely amalgamated with the laminae. There is therefore no danger of any further displacement.

Fig. 3.—Diagram of method used.

The iron wire will not be removed unless it causes trouble, which is extremely unlikely. The patient considers himself entirely cured and has resumed his former occupation and habits. He is not conscious of any limitation of motion in his neck.

#### COMMENT

This case demonstrates the inadvisability of wiring together the cervical spinous processes through drill-holes, as they are not strong enough, when drilled, to stand the stress. It also shows that a longer period of recumbency, probably three months instead of two, is required to produce an unyielding bony fusion.

The approximation of the spinous processes by ligature is an uncommon operation. Cotton<sup>1</sup> had an almost identical case. The patient was an "iron-puddler," and the sixth and seventh cervical vertebrae were involved. Cotton laced a wire "back-stay" about the spinous processes of these vertebrae with a successful result. The operation was described by Hadra<sup>2</sup> in 1891, and W. A. Lane<sup>3</sup> in 1892, in describing a fracture dislocation of the spine, wrote: "I passed a stout silk ligature between the spinous processes of the ninth, tenth, eleventh and twelfth dorsal vertebrae, and by that means tied the tenth and eleventh spinous processes immovably together." There was at least a temporary recovery in this case.

Fig. 4.—Thirteen months after operation: slight recurrence of displacement, but solid fusion of articulations and laminae; complete functional recovery.

Fig. 2.—a, condition five weeks after operation: fracture of the spinous process of the sixth cervical vertebra through the drill hole. b, condition after second operation. Wire has been passed beneath the lamina of the sixth cervical vertebra and under the spinous process of the seventh cervical vertebra. Slightly retouched.

(fig. 3). The neck was extended by an assistant, and as the wire was tightened the vertebrae came easily into normal alignment and were held firmly by the strong wire.

In order to produce a bony ankylosis (fusion), thin slips of bone were cut with a rongeur from the sixth and seventh laminae and placed across the laminae, like bridges. It was not deemed safe to use the ordinary gouge and mallet in cutting these slips. The lateral articulations (true joints) between the sixth and seventh vertebrae were curetted, to cause an arthrodesis. Two pieces of cortical bone, cut from the tibia, about  $1\frac{1}{2}$  by  $\frac{3}{8}$  by  $\frac{1}{4}$  inch, were laid on the denuded sixth and seventh laminae, with several small chips. This provided a continuous mass of bone tissue, probably osteogenic, and certainly furnishing the constituents of bone production. The wound was closed in layers, and the thorax, neck and head were placed in a plaster-of-paris half-shell, which had been previously prepared.

Again the patient made a very satisfactory convalescence. Postoperative x-ray examination (fig. 2b) showed perfect replacement of the dislocation. February 13 an unsightly, depressed portion of the scar was excised under local anesthesia.

The patient was discharged from the hospital March 15, a little over two months after the fusion operation. He wore the

## NATIONAL FOOD, DRUG AND COSMETIC LEGISLATION

Two bills<sup>1</sup> are now pending in Congress, each drafted with a view to the removal of the weaknesses inherent in the Food and Drugs Act of 1906. Each bill is designed, however, to go further and (1) to establish standards of purity for cosmetics, (2) to establish standards of truthfulness for the labeling and advertising of cosmetics and prophylactic and therapeutic devices, and (3) to establish methods of law enforcement more effective than those now authorized. Each of these bills is better calculated to protect and promote the public health and to enforce care, skill and honesty in manufacturing and merchandising than were the corresponding bills passed by the Senate and the House of Representatives in the Seventy-Fourth Congress, which failed in conference. There is, however, still much room for needed improvement.

Each bill, for instance, proposes to authorize every manufacturer and dealer in drugs who is within its purview to fix his own private standards of strength for such drugs as are defined in the United States Pharmacopeia and the National Formulary and even for such drugs as are defined in the Homeopathic Pharmacopeia of the United States. The Senate bill goes further and proposes to permit similar tampering with established standards of quality and purity as well as with the standards for potency. If either of these bills is enacted in its present form, no drug defined in any of these books of supposed authority or in any supplement to any such book is to be deemed adulterated because it differs from the standard of strength there set forth, provided only that it conforms to any standard whatever that is plainly stated on the label. How a statement on the label of a container on the shelves of a dispensing pharmacist is to afford protection to the patient for whom a physician, in reliance on his knowledge of pharmacopeial and formulary standards, prescribes any

potent drug, such as tincture of opium or tincture of nux vomica, is difficult to understand.

The standards proposed for "patent" and proprietary medicines are about as bad as the free-for-all standards for official remedies. Both bills provide that a drug which is not recognized by the United States Pharmacopeia, the Homeopathic Pharmacopeia of the United States or the National Formulary, or by any supplement to any of them, shall be deemed to be adulterated if its identity or strength differs from, or its quality or purity falls below, that which it purports or is represented to possess. But neither bill requires a manufacturer or dealer in drugs to make any representation as to just what the strength of his "patent" or proprietary medicine is. How little protection such legislation will afford the consumer of such nostrums is obvious. Manufacturers and dealers in "patent" and proprietary medicines are to be further protected, if the bill pending in the House of Representatives is enacted, for this proposes to exempt any maker or dealer of any medicine fabricated from two or more ingredients from the duty of disclosing on the label the name of each active ingredient, provided only that he has disclosed such ingredients fully and correctly to the Secretary of Agriculture. The very purpose of such legislation is to facilitate secrecy, and the fact that an invalid who resorts to self medication and ought to know what he is taking is kept in the dark seems to have been regarded as immaterial. The House of Representatives bill makes it clear that, notwithstanding such exemption from the disclosures of formulas on labels, labels must bear statements of the quantity, kind and proportion of alcohol. The phraseology leaves it extremely doubtful, however, whether barbituric acid, chloral, morphine or any other of the important group of narcotic and hypnotic drugs named in the bill, if it happens to be an active ingredient of any "patent" or proprietary medicine, must be declared on the label or whether the disclosure of its presence to the Secretary of Agriculture will not relieve the manufacturer or dealer from any such obligation.

The Senate and the House of Representatives bills contain provisions intended to regulate the sale in interstate commerce of all devices intended for use in the diagnosis, cure, mitigation, treatment or prevention of disease in man or other animals or intended to affect the structure or any function of the body. Neither bill, however, undertakes to lay down any standards of structural safety, of accuracy or of potency for any such device, nor does either provide any way in which any such standard may be established. The provisions of both bills with respect to the misbranding of devices seem inadequate, for while an effort has been made to make applicable to devices the standards of labeling that apply to drugs, the basic labeling requirement, which applies only to drugs and devices "in package form," will not be applicable to the many important diagnostic, prophylactic and therapeutic devices used by physicians

<sup>1</sup> S. 5, introduced by Senator Sheppard of Texas, for Senator Cope-land of New York; H. R. 300, introduced by Representative Chapman of Kentucky.

## Special Article

### THE PHARMACOPEIA AND THE PHYSICIAN

### RESPIRATORY STIMULANTS AND THEIR USES

YANDELL HENDERSON, Ph.D.

NEW HAVEN, CONN.

*This is one of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed.*

Normal respiration is closely coordinated with other functions, such as the liberation of energy, combustion of carbonaceous materials, consumption of oxygen, and particularly the production of carbon dioxide. Any drug that disturbs this relation of respiration to metabolism for more than a brief period seriously upsets the economy of the body. This is the fundamental consideration that must always be kept in mind in choosing and using respiratory stimulants. Only such drugs as are free from this objection are permissible.

Recognition of this limitation properly excludes many substances from use as respiratory stimulants, although they may be used for other purposes. For instance, several of the anesthetics—such as ether and nitrous oxide in the first stage of their effects—induce a large increase in the volume of breathing. This overventilation of the lungs may induce so great a decrease in the carbon dioxide content of the blood that a compensatory decrease of respiration, or even a complete standstill, follows. This tendency to apnea is manifested in the later stages of ether anesthesia, for under full etherization the action of the drug is reversed and respiration is depressed. Failure of respiration under anesthesia is thus quite as much the result of the acapnia produced by the stimulation of respiration in the first stage of anesthesia as it is of the depression that the drug induces in the later stages.<sup>1</sup>

Such respiratory stimulation without a corresponding stimulation of metabolism occurs under a wide variety of substances; e. g., small doses of cyanide and sulfide, monoiodoacetic acid and many others. Each of these drugs has, in addition to its influence on respiration, other effects also that are undesirable.

#### STIMULATION BY INCREASE OF METABOLISM

Turning then from such undesirable stimulants, one can include in the class of allowable drugs only those that act largely on and through metabolism as well as by direct stimulation of respiration itself. The outstanding member of this group—other than carbon dioxide—is caffeine, which in the form of coffee is a most valuable respiratory stimulant. That the effect of coffee is due chiefly to caffeine is demonstrated by the fact that not only the rate and depth of breathing but the general processes of metabolism as well are increased. There is an increased consumption of oxygen and increased heat production, owing probably

to the augmented tonus of the musculature of the body. All these stimulations are most marked in the first ten or fifteen minutes but wear off in the course of a few hours and may in some persons be followed by a distinct feeling of lassitude.

In this class of indirect respiratory stimulants the next most important drug is strychnine. A generation or more ago, when it was customary to prescribe a tonic for all patients who were "run down," strychnine, more commonly than any other medicine, was taken in various mixtures "three times daily, after meals." Strychnine was then regarded as a heart stimulant. Modern pharmacology however has demonstrated conclusively that strychnine has no such direct action on the heart and that its chief effects are the accentuation of the spinal reflexes and the consequent increase of muscle tonus. Yet, properly understood, this action is sufficient to constitute strychnine as having an auxiliary effect on both the heart and respiration. The tonus of the muscles of the body is a major factor in the heat production, oxygen consumption and carbon dioxide production of the body; and the amount of carbon dioxide produced determines the volume of respiration. The tonus of the musculature of the body likewise induces an intratissue pressure that plays a large part in the volume of the venous return to the right side of the heart. And as the volume of the venous return is a principal factor in the volume that the heart pumps into the arteries, muscle tonus largely determines the volume of the circulation. When muscle tonus is low, the heart action is diminished. By its influence on the motor centers in the spinal cord, strychnine increases muscle tonus, the intratissue pressure, the venous return and the efficiency of the heart.<sup>2</sup>

Far more powerful than either caffeine or strychnine as a stimulant to metabolism, and indirectly to respiration, is dinitrophenol. The hazard to health and the high liability to overdosage and death involved in the use of this drug are, however, so great that it should be regarded as essentially a poison.

In European practice lobeline—and the similar drug coramin—has found some advocates in such conditions as carbon monoxide poisoning; but its effect on respiration, although powerful, is brief, and it is a cardiac depressant. Even in Europe the use of lobeline appears now to be giving way to inhalational treatment. In America, where stimulation of respiration by inhalation of carbon dioxide is now fully established, the only condition in which lobeline has been used is asphyxia neonatorum. When injected directly into the umbilical vein, it causes a brief succession of powerful inspiratory gasps.<sup>3</sup> But its use in this condition has been challenged.

#### ANTIDOTES AGAINST RESPIRATORY DEPRESSION

Aside from the use of caffeine and strychnine in therapeutic doses to induce a prolonged moderate increase of respiration by increase of metabolism, both of these drugs and a number of others are used in much larger dosage as antidotes to counteract imminent respiratory failure due to poisoning by respiratory depressants. The depressants are commonly morphine and the barbiturates. As an antidote to the barbiturates, strychnine is particularly effective: as the barbiturates are also against strychnine.<sup>4</sup> Against morphine the

that must be weighed and resolved by the experience of legislators who have the matter in charge. What the public undoubtedly wants is the prompt enactment of effective legislation, followed by appropriations adequate for the effective enforcement of whatever law may be written on the statute books.

### EDUCATION OF THE PUBLIC ON SYPHILIS—A WARNING!

The Advisory Committee to the U. S. Public Health Service<sup>1</sup> has included as an important element of a program for the control of syphilis "the preparation and dissemination of educational material to the general public." Use of radio broadcasts, pamphlets, motion pictures, lectures, exhibits and the press was suggested. For the press the caution was voiced: "Brief statements from authoritative sources should be prepared for the press."

One of the foremost obstacles to the success of a campaign against syphilis is the tabu that has until recently applied to the word "syphilis." The conspiracy of silence that has prevented the dissemination of fundamental information concerning the disease to the nonmedical public has been unfortunate. The situation as to syphilis today is analogous to that of tuberculosis a generation and a half ago. Much of the progress that has been made in the control of tuberculosis is due to the widespread and constant educational publicity given to this disease. Informative publicity concerning syphilis is a valuable method, perhaps the most valuable method, of aiding in the two fundamental points of public health control efforts: (1) finding patients with syphilis and bringing them under competent medical care and (2) holding them under treatment for a long enough period to ensure the maximum result as to individual and public safety.

Informative publicity to the lay public should (a) avoid the implication of reform of public morals by legislative fiat and should stress the medical aspects of the control program, (b) be scientifically sound and accurate and (c) be prolonged over a period of many years.

Publicity as to syphilis is now becoming widespread. Until recently, except for a brief three year period, nothing about the disease, not even its name, could be forced into the public press. Within the last two years, conservative and liberal newspapers and magazines alike—the *New York Times*, *Herald Tribune* and *Daily News*, the *Chicago Tribune*, the *Baltimore Sun*, the *Washington Herald*, *Time*, the *Literary Digest*, the *Readers' Digest*, the *Ladies' Home Journal*, to mention only a few of the 125 periodicals of some 100 communities (up to Oct. 26, 1936—see *Time* for that

date)—had mentioned "syphilis" and had printed news stories, editorials or important feature articles concerning it. Now books are being published for the public and at least three leading magazines have scheduled articles for early appearance. In journalistic parlance, the subject is "hot."

Every one knows that a flood of misinformation may do more harm than good. Overemphasis on moral reform, on "social hygiene," and underemphasis on the more easily defensible medical approach are possibilities. Even more dangerous is the publication of such scientific misinformation as suggests (*Literary Digest*, Oct. 31, 1936) that syphilis may be "cured" by one inadequately studied method of treatment in three months, or by another in two weeks.

Another serious danger is the fact that the publicity gives evidence of being concentrated within too short a period. Since current public interest is greater than can be satisfied by medical accomplishment, interest may evaporate faster than it can be appeased. Those who wish to educate will have shortly said all there is to say and will have nothing new to offer, only repetition. Editors and audience alike will treat the subject as the latest fad, wearying of it as quickly as they have wearied of such other great American fads as flagpole sitting or miniature golf. It is possible, and at the present rate likely, that the syphilis control program will be talked to death.

Success in the campaign to control syphilis cannot be attained in a year or two or even in five or ten years. Success, if it comes at all, is to be measured in the same long terms as in the campaign to control tuberculosis—a generation, two generations. What is needed is not a flood of publicity for a few months or years but persistent publicity for many years. Syphilis must be kept as constantly in the public mind as tuberculosis has been kept, and for as long a time.

This is not the first American campaign to control syphilis or the first time that publicity in the press has been given to it. From 1918 to 1920 a similar effort began under almost equally favorable auspices and met with dismal failure. The immediate impetus was the protection from venereal diseases of American soldiers. Large sums of money were appropriated by Congress and the states, and a brave start was made; it collapsed completely within three years. In retrospect, the causes of the failure of this earlier effort seem clear. The first and most usually assigned cause was the withdrawal of federal and state financial support that accompanied the subsidence of war hysteria and the postwar period of retrenchment. This withdrawal of funds, however, was not due to these two factors alone but to lack of public interest and public support. Public interest and support apparently failed for more fundamental reasons: the syphilis control campaign at that time was based largely on "social hygiene" and moral reform, the American people were reacting against the

J., and Usilton, Lida J.: Recommendations for a Venereal Disease Program in State and Local Health Departments: Report of an Advisory Committee to the United States Public Health Service, Ven. Dis. Inform. 17:1 (Jan.) 1936.

ing or poorly breathing baby as it is for the victims of carbon monoxide. In the baby, as in the adult, a slight deficiency of oxygen at first renders the respiratory center more sensitive than normally to carbon dioxide, and this increased sensitivity to that stimulus helps the normal baby to start breathing. Under severe deficiency of oxygen, on the contrary, the sensitivity of respiration is greatly decreased, and the deeper the asphyxia at birth the greater the amount of carbon dioxide required to stimulate respiration. The carbon dioxide employed for the initial resuscitation should be of whatever strength is needed to induce respiration, but after respiration is started 7 per cent or even 5 per cent is generally sufficient.<sup>9</sup>

Even more important is the use thereafter of carbon dioxide to promote full expansion of the lungs and the establishment of vigorous breathing in premature or otherwise weak babies. For such babies the inhalation of 5 or 6 per cent carbon dioxide should be repeated several times during the first few days. The present high mortality of the first week or two of life may thus be greatly diminished.

For the woman in whom a prolonged labor and overbreathing have induced a considerable degree of acapnia, fatigue and muscular relaxation, inhalation of 5 per cent carbon dioxide in air or oxygen is helpful. It tends to restore tonus and promote effective expulsive contractions of both the uterus and the abdominal muscles.<sup>10</sup>

In the early stages of pneumonia, inhalation of carbon dioxide has been used as a means of dilating the lungs and inducing coughing, to clear them. (In the hands of Drs. Lewis Gunther and Harry H. Blond<sup>11</sup> this use of inhalation has produced promising results in shortening the disease and lowering its mortality, results which I have been privileged to see.) In fully developed pneumonia, oxygen is now often administered. The inhalation is more effective if some of the carbon dioxide exhaled by the patient is allowed to accumulate in the oxygen tent. One or two per cent is not noticed by the patient; higher percentages render him uncomfortable but probably increase the chances of recovery.<sup>12</sup>

In patients with effort angina, moderate inhalations of carbon dioxide for ten or twelve minutes two or three times a day may afford a partial substitute for physical exercise and some of the benefits of the Nauheim baths.<sup>13</sup>

Inhalation of carbon dioxide—best diluted merely with air—is an effective means of controlling persistent hiccup.<sup>14</sup>

The sufferings of morphine addicts during withdrawal of the drug may be considerably diminished by inhalation of carbon dioxide.

#### METHODS OF ADMINISTERING CARBON DIOXIDE

For the administration of carbon dioxide diluted either with oxygen or with air, several types of

inhalators are employed; each has a purpose and mode of use distinct from the others.

In anesthesia apparatus a cylinder of carbon dioxide is now generally provided and the anesthetist adjusts the mixture of this gas with oxygen, ethylene, nitrous oxide, ether, and so on, as the condition of the patient and the demands of the surgeon require.

In the inhalators used by the rescue crews of city fire and police departments<sup>15</sup> the cylinders are charged with a mixture of 7 or 8, or even 10, per cent of carbon dioxide in oxygen. The gas flows through a bag to a mask, which should be held tight on the face of the patient—usually a victim of carbon monoxide—so that the gas is inhaled without admixture of air. The valves on the mask are so arranged that there is no rebreathing whatever, and the lungs are flushed with entirely fresh gas at each breath.

For cases of asphyxia neonatorum this form of inhalator is also effective. A simpler form<sup>16</sup> is however, quite adequate. It involves merely a cylinder of the gas mixture, a needle control valve, a breathing bag and a tight fitting mask. For the new-born, rebreathing need not be avoided; indeed, it is rather desirable. A mild form of artificial respiration—to replace mouth to mouth inflation—is induced by squeezing the breathing bag intermittently, while the mask is held tight on the face, with the head of the baby in hyperextension, so as to keep the pharynx open. For severe cases of asphyxia and apnea, particularly in babies born of heavily narcotized mothers, the gas should at first be administered through a sound inserted deep into the trachea.<sup>17</sup>

For many purposes—e. g., control of hiccup, prevention of postoperative atelectasis or clearing the lungs in early pneumonia—it is not necessary to use mixtures of carbon dioxide with oxygen. Carbon dioxide alone, mixed with air as it is inhaled, is sufficient and is much less expensive.<sup>16</sup> The flow is regulated by a needle valve and measured on a water manometer, which also serves as a safety blow-off. The gas is administered by means of an open or "slotted" mask. The patient is first allowed to breathe air alone through a hole in the top of the mask or through a slot in its side. Then very gradually the gas is turned on so as to mix with the air inspired through the mask. And as respiration responds, the flow of carbon dioxide is increased until the depth of breathing is nearly or quite maximal. But the respiratory rate should not be increased.

For children threatened with bronchitis, and for premature babies subject to spells of respiratory depression and cyanosis, a small injector tent is convenient.<sup>16</sup> The volume of the gas flowing from a cylinder of carbon dioxide is regulated and measured by a needle valve and manometer and is introduced into the top of the tent through an injector, which automatically mixes it with air in a proportion of from 3 to 6 per cent of carbon dioxide. The stimulation of respiration and the circulation thus induced is much more effective in overcoming cyanosis and increasing vitality than is the inhalation of oxygen without carbon dioxide. With full respiration the blood takes up nearly as much oxygen from air as from pure oxygen. Without an adequate volume of breathing, the baby can die of asphyxia in an atmosphere of oxygen.

tion mouthpiece and from the cylinders for patch tests. The collecting of these materials itself caused severe dermatitis, the edema of the face and eyelids being so extensive that the patient's left eye was completely closed. Patch tests of both the dust from the machine and the scrapings from the cylinders were strongly positive, whereas no reaction was obtained from the scrapings from the mouthpiece. No reaction to any of these substances occurred in normal control subjects. With the cooperation of the company manufacturing the machines, patch tests were made with three of the substances employed in the manufacture of the cylinders; namely, aluminum stearate, stearic acid and pine tar. All gave negative tests. The patient was advised to avoid all unnecessary contact with the dictaphone, and the machine was placed in a part of the office free from drafts and was cleaned at night. By following these precautions, the patient has remained free from symptoms for more than a year.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### CALIFORNIA

**Bills Introduced.**—S. 98 proposes to prohibit the planting, cultivating, harvesting and processing of "any flowering tops or leaves of hemp or loco weed (*cannabis sativa*) or Indian hemp" and to make a violation of the prohibition a felony. S. 118 proposes to prohibit the operation or maintenance of a clinical laboratory except under the immediate supervision and direction of a licensed clinical laboratory technologist or of a person holding a valid and unrevoked physician's and surgeon's certificate. The bill proposes to make it unlawful for any person in a clinical laboratory to make any tests or examinations requiring the application of one or more of the fundamental sciences, such as bacteriology, biochemistry, serology and parasitology, unless he possesses an unrevoked certificate, issued by the state board of health, as a qualified technician in the subject or subjects concerned with the tests or examinations, or possesses an unrevoked certificate as a clinical laboratory technologist, or is the holder of a valid unrevoked physician's and surgeon's certificate. The state board of health is authorized to license as a clinical laboratory technologist (1) any person who for more than five years has been engaged actively in the work and direction of a clinical laboratory and (2) any other person who is found to be properly qualified, by written, oral and practical examination. The board is to be authorized also to license as a clinic or laboratory technician (1) any person who for three years has actively engaged in performing tests in a clinical laboratory and (2) any other person found by it to be properly qualified, by written, oral and practical examinations. S. 121, to supplement the insurance code, proposes to authorize insurance whereby the insurer will provide medical and hospital services in case of need, to regulate the conditions under which such insurance may be written, and to require the licensing of persons writing such insurance contracts. S. 133 proposes, in the event a business and professions code is enacted by the fifty-second legislature, to repeal the existing medical practice act and to enact in its stead as chapter 5, division II, of the proposed business and professions code a comprehensive new medical practice act regulating the practice of medicine and surgery, chiropody, midwifery and drugless healing other than chiropractic and osteopathy which are governed by initiative measures adopted in 1922. A. 644, to amend the workmen's compensation act, proposes to permit an injured employee "to select, without restraint, any one licensed to treat in any manner the type of injury which he has sustained." A. 684 proposes to authorize county or city and county boards of education to "grant health and development certificates to physicians and surgeons holding certificates issued by the California State Board of Osteopathic

Examiners." This law now authorizes the issue of such certificates only to persons holding certificates to practice medicine and surgery, issued by the California State Board of Medical Examiners.

### DELAWARE

**Society News.**—Dr. Arthur C. Morgan, Philadelphia, addressed a combined meeting of the Kent and Sussex county medical societies in Milford, December 2, on "Diagnosis and Treatment of Acute Cardiac Tragedies."—Dr. Thomas Fitz-Hugh Jr., Philadelphia, addressed the New Castle County Medical Society in Wilmington, January 19, on "Use of Prontosil and Prontylin in Hemolytic Streptococcus Infections."

### DISTRICT OF COLUMBIA

**Medical Bill in Congress.**—*Bill Introduced:* H. R. 3890, introduced by Representative Quinn, Pennsylvania, proposes to prohibit experiments on living dogs in the District of Columbia.

### IDAHO

**Bill Introduced.**—S. 33, to amend the workmen's compensation act, proposes to make compensable "such disease or infection as may arise naturally out of" the employment.

### ILLINOIS

**Forty or More Years of Service.**—The Kankakee County Medical Society observed its forty-fifth anniversary, December 11, by honoring the following members, who have completed more than forty years' practice in the county:

Dr. George W. Van Horne, Grant Park, began practice sixty-one years ago.

Dr. Eugene D. Bergeron, Kankakee, fifty-five years.  
Dr. G. M. Phelps, Kankakee, fifty years.  
Dr. Aaron S. Eshbaugh, Kankakee, fifty years.  
Dr. Stanley R. Walker, Chebanse, forty-seven years.  
Dr. John A. Brown, Kankakee, forty-three years.  
Dr. Fred C. Hamilton, Kankakee, forty-three years.  
Dr. Arthur N. House, Kankakee, forty-three years.  
Dr. Ulric A. Bedard, Kankakee, forty-two years.  
Dr. John V. Lewis, Momence, forty-two years.  
Dr. Charles W. Geiger, Kankakee, forty years.  
Dr. Samuel A. Worstall, Aroma Park, forty years.

All the physicians except Dr. Van Horne are still in practice. Dr. Walker was the first vice president in 1891 and is now president. Dr. Chester A. Perrodin, Kankakee, is secretary. At the anniversary meeting Dr. Leroy H. Sloan, Chicago, presented a paper entitled "Modern Docology," a tribute to the guests of honor.

### Chicago

**The Lewis Linn McArthur Lecture.**—Dr. Wingate Todd, Henry Willson Payne professor of anatomy, Western Reserve University School of Medicine, Cleveland, will deliver the thirteenth Lewis Linn McArthur Lecture of the Frank Billings Foundation, February 26. His subject will be "Objective Ratings on the Constitution; Based upon Examinations of Physical Development and Mental Expansion in the Growing Child."

**Meeting of Bacteriologists.**—A meeting of the Society of Illinois Bacteriologists was held at the Chicago Woman's Club, January 23, with the following speakers:

Dr. Sol R. Rosenthal, associate in the department of pathology, bacteriology and public health, University of Illinois College of Medicine. Cellular Response in the Host to Antigenic Substances.  
James Russell Esty, Ph.D., research director, Western branch, National Canners' Association, San Francisco, Bacteriological Problems of the Canning Industry.

### INDIANA

**Committee on Syphilis Control.**—The Indiana State Medical Association has appointed a committee on syphilis control. Dr. Floyd R. Nicholas Carter, South Bend, is chairman; other members are Drs. Minor W. Miller, Evansville, and Ernest O. Nay, Terre Haute.

**Bills Introduced.**—H. 53, to amend the workmen's compensation act, proposes, in effect, to make compensable any "disease arising out of the employment." H. 146, to amend the law requiring a physician appointed by the court in proceedings to commit allegedly feeble-minded persons to examine the person and to certify whether or not the person is afflicted with idiocy, imbecility or feeble-mindedness, proposes to require such physician to certify further whether, in his opinion, "the welfare of society and of such person would be promoted by his or her sexual sterilization." H. 147, to amend the law authorizing the sexual sterilization of inmates of state institutions who are afflicted with hereditary forms of insanity that

normally born infants begin to breathe only after an apnea and asphyxial gasps, as many now do, the drugging of the mothers is excessive.

As nitrous oxide is one of the anesthetics now commonly used in labor, attention should be drawn to Eastman's<sup>22</sup> warning that the amount of oxygen administered with the gas should be kept above 15 per cent, and that if it falls to 10 per cent or less a marked degree of fetal anoxemia may be produced and "occasionally profound asphyxia neonatorum results." Neglect of this general precaution in surgical operations under nitrous oxide has recently been shown by Courville<sup>23</sup> to result in some cases in nervous sequelae and deaths essentially like those following prolonged carbon monoxide asphyxia.

The properties of drugs desirable for use in obstetrics are in many respects different from those desirable for surgical operations. In both fields the prevention of suffering should be as complete as possible without inducing damage. But the surgeon deals with only a single patient, the obstetrician with two. And the fact is now too often overlooked that the science of pharmacology affords no means of rendering childbirth free from even the slightest discomfort or recollection in the mother, except at the price of an occasional infant life.

4 Hillhouse Avenue.

## Council on Foods.

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

#### STOKELY'S FINEST TOMATO JUICE

*Manufacturer.*—Stokely Bros. & Company, Inc., Indianapolis.

*Description.*—A canned pasteurized tomato juice, seasoned with salt, retaining in large measure the original vitamin content of the tomatoes used.

*Manufacture.*—Field control and inspection of deliveries are exercised to insure the receipt of sound tomatoes, at the height of color and flavor, which are washed in troughs of running water, rolled through reel washers equipped with water sprays for thorough rinsing, sorted and trimmed on continuous belts, and the underripe and overripe fruit eliminated. The selected clean tomatoes then pass through a preheating chamber with controlled temperature conditions. The juice is extracted, without being exposed to the air, by a method which produces a juice of thin consistency retaining solid material essential for providing vitamin A. The juice passes immediately to stainless steel salting tanks and from there to the filling machines, where it is filled into enamel lined cans at a temperature between 80 and 85 C. and pasteurized for a definite period. The factory process is under laboratory control and every precaution is taken to avoid contact with air to minimize vitamin destruction.

*Analysis* (submitted by manufacturer).—Moisture 93.9%, total solids 6.1%, total ash 1.1%, salt (sodium chloride) 0.5%, fat (ether extract) 0.1%, protein ( $N \times 6.25$ ) 0.9%, acidity (as citric acid) 0.4%, crude fiber 0.1%, total invert sugar 2.7% and total carbohydrate (by difference) 3.5%.

22. Eastman, N. J.: Fetal Blood Studies: V. The Role of Anesthesia in the Production of Asphyxia Neonatorum, *Am. J. Obst. & Gynec.* 31: 563 (April) 1936.

23. Courville, C. B.: Asphyxia as a Consequence of Nitrous Oxide Asphyxia, *Medicine* 15: 129 (May) 1936.

*Calories.*—0.25 per gram; 7.1 per ounce.

*Vitamins.*—The use of mature tomatoes, the careful factory control, the continuous method of manufacture, and the avoidance of contact with air assure maximum retention of the normal vitamin content.

*Claims of Manufacturer.*—This tomato juice is a good source of vitamins A and B<sub>1</sub>, and an excellent source of vitamin C. It is suitable for infant feeding and for general table use.

#### POCAHONTAS "FRESHLIKE" STRAINED UNSEASONED PRODUCTS (PEAS, CARROTS, BEETS, SPINACH, GREEN BEANS, TOMATOES, CELERY, APPLES, PRUNES, APRICOTS AND VEGETABLES WITH CEREAL AND BEEF BROTH)

*Distributor.*—H. P. Taylor Jr., Inc., Richmond, Va.

*Packer.*—The Larsen Company, Green Bay, Wis.

*Description.*—Respectively strained peas, spinach, carrots, beets, green beans, celery, tomatoes, prunes, apples, apricots and vegetables with cereal and beef broth; prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. These products are the same as the respective accepted Larsen's vegetables and fruits (*THE JOURNAL*, Aug. 26, 1933, p. 675; Aug. 12, 1933, p. 525; Aug. 19, 1933, p. 605; July 8, 1933, p. 125; July 29, 1933, p. 366; Sept. 2, 1933, p. 779; July 1, 1933, p. 35; July 22, 1933, p. 282; Aug. 10, 1935, p. 437; July 4, 1936, p. 38; July 22, 1933, p. 283).

#### CELLU JUICE-PAK RED PITTED CHERRIES

*Distributor.*—The Chicago Dietetic Supply House, Inc., Chicago.

*Packer.*—Reynolds Preserving Company, Sturgeon Bay, Wis.

*Description.*—Processed, pitted red cherries packed in undiluted juice without added sugar.

*Manufacture.*—The manufacturing process is essentially the same as that for Cellu Juice-Pak Royal Anne Cherries (*THE JOURNAL*, Aug. 25, 1934, p. 564).

*Analysis* (submitted by manufacturer).—Moisture 84.2%, total solids 15.8%, ash 0.4%, fat (ether extract) 0.8%, protein ( $N \times 6.25$ ) 0.8%, sucrose 0.1%, reducing sugars as invert sugar 10.5%, crude fiber 0.2% and carbohydrates other than crude fiber (by difference) 13.6%.

*Calories.*—0.65 per gram; 18.5 per ounce.

#### SEXTON BRAND BLACK RASPBERRIES, WATER PACKED

*Manufacturer.*—John Sexton & Company, Chicago.

*Description.*—Canned black raspberries, packed in water.

*Manufacture.*—Black raspberries picked at the proper stage of maturity are inspected, mechanically washed and filled into cans. The cans are filled with water, exhausted, sealed and processed at 91 C.

*Analysis* (submitted by manufacturer).—(Analysis of entire contents including liquid): moisture 88.6%, total solids 11.4%, ash 0.23%, fat (ether extract) 1.1%, protein ( $N \times 6.25$ ) 1.1%, crude fiber 3.20%, carbohydrates other than crude fiber (by difference) 5.8%.

*Calories.*—0.37 per gram; 10.5 per ounce.

*Claims of Manufacturer.*—For diets in which sweetened fruit is proscribed.

#### BERKSHIRE HILLS BRAND HAWAIIAN PINEAPPLE CRUSHED, SLICED AND TIDBITS

*Distributor.*—Butler Flour Company, Pittsfield, Mass., and Butler Coal & Grain Company, Adams, Mass.

*Packer.*—Hawaiian Pineapple Company, San Francisco.

*Description.*—Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole canned pineapple (*THE JOURNAL*, April 8, 1933, p. 1106).

## MISSOURI

**Survey of Public Health Administration.**—The U. S. Public Health Service is making a survey of public health administration in Missouri, according to the *Health Officer*. When it is completed, a report will be furnished to the governor's commission which is studying the application of the Social Security Act in the state.

**Personal.**—Dr. Curtis H. Lohr has been appointed superintendent of St. Louis County Hospital, Clayton, succeeding Dr. Edwin L. Sheahan, it is reported.—Dr. Silas Sanford recently completed fifty years of practice in Palmyra.—William R. Goodman, founder and former president of the Blood Donors Benevolent Society of Missouri, was presented with a certificate by the St. Louis Medical Society recently for "meritorious service"; the organization was formed in January 1935 and now consists of 475 members who give blood for transfusion free for persons unable to pay.—Dr. John W. Williams Jr., Springfield, has been appointed director of local health work in the Missouri State Department of Health. Dr. Williams graduated from Washington University School of Medicine in 1923 and has specialized in public health work. He was formerly health officer of Greene County and became associated with the state health department in the summer of 1936.

## NEVADA

**New Official Organ for the State Medical Society.**—The Nevada State Medical Association announces that the *Utah State Medical Journal* will henceforth be its official organ, instead of *California and Western Medicine*. The Utah journal will publish the transactions of the Nevada society, news items and announcements. Dr. Horace J. Brown, Reno, secretary of the association, will act as editor.

## NEW JERSEY

**Society News.**—Dr. Howard W. Haggard, New Haven, Conn., among others, addressed the New Jersey Conference of Social Work at its annual meeting at Asbury Park, December 3-5, on "Health and Social Change."—Dr. Irving S. Wright, New York, addressed the Monmouth County Medical Society, Asbury Park, December 16, on "Peripheral Vascular Diseases of the Extremities."—Dr. Thomas K. Lewis, Camden, addressed the Salem County Medical Society, December 11, in Salem on cardiac irregularities.—Dr. Donald C. Richards, Easton, Pa., addressed the Warren County Medical Society, Washington, December 8, on obstetric anesthesia.

**Symposium on Tuberculosis.**—Bergen County Hospital, Ridgewood, presented a symposium on tuberculosis, January 19, at which the guest speakers were Drs. Robert E. Plunkett of the New York State Department of Health, Albany, on "The Essential Role of the Family Physician in the Campaign Against Tuberculosis"; James Burns Amberson Jr., New York, "Childhood Tuberculosis," and William J. Ryan, Pomona, N. Y., who opened the general discussion. Other speakers were Drs. Oddino Bernardini and Joseph Gordon of the staff on "X-Ray Versus Stethoscope" and "Pulmonary Hemorrhage" respectively. There were also presentations of cases, a pathologic exhibit, a demonstration of tuberculin testing and discussion of unusual roentgenograms.

## NEW YORK

**Bill Introduced.**—A. 260 proposes to authorize the commissioner of motor vehicles to reimburse hospitals not organized and/or operated for profit, for the cost of care rendered indigent persons suffering from motor vehicle injuries. The amount of reimbursement to such a hospital is to be limited to not more than \$6 for each day of care rendered to each indigent.

## New York City

**Dr. Held Honored.**—Colleagues and former students of Dr. Isidore W. Held, clinical professor of medicine, New York University Medical College, contributed to the *Review of Gastro-Enterology* for December in honor of his sixtieth birthday. Dr. Held is attending physician at Beth Israel Hospital, where the pathology laboratory is named in his honor.

**Meeting on Heart Disease.**—The New York Heart Association (the heart committee of the New York Tuberculosis and Health Association) will hold its annual meeting at the New York Academy of Medicine, February 9. The speakers will be Drs. John L. Caughey Jr., on "Clinic Studies of Venous Pressure"; Nathaniel T. Kwit, "The Nanthines in the Treatment of Cardiac Pain," and Janet G. Travell, "Theophylline in Experimental Myocardial Infarction."

**District Health Officers Appointed.**—Three new district health officers were assigned from a civil service list December 16: Drs. Jacob Rosenbluth, chief diagnostician of the city health department since 1928; Harold H. Mitchell, recently president of the New York State Association of School Physicians, and William F. Wild, Suffolk, Va., health officer of Suffolk and the counties of Nansemond and Isle of Wight. Dr. William C. Buntin, Staten Island, was made health officer of the Borough of Richmond.

**Dinner to Dr. Arcé.**—The New York Chapter of the Pan American Medical Association sponsored a dinner in honor of Dr. José Arcé, professor of surgery and dean of the University of Buenos Aires and dean of the Argentine chapter of the association, January 11, at the Metropolitan Club. Drs. Adolfo F. Landivar, Antonio Egues and Isidro Castillo Odena, professors of surgery at Buenos Aires, who are with Dr. Arcé on his visit to the United States, were also guests of honor. Dr. Arcé gave an address on "The Future of Pan American Medicine"; other speakers were Drs. Charles Gordon Heyd, President of the American Medical Association, James Ewing of Memorial Hospital, and Dean Lewis, Baltimore. Dr. Edward L. Kellogg, president of the New York chapter, was toastmaster.

## NORTH DAKOTA

**Bill Introduced.**—S. 67 proposes that no sales tax or other levy of any nature shall be payable on sales of equipment, medicine, drugs or supplies to any institution of public charity, including public hospitals under the control of religious or charitable societies.

## OHIO

**Home Donated for Health Museum.**—Mrs. Francis F. Prentiss, Cleveland philanthropist, has given her former residence on Euclid Avenue to house a museum of health and hygiene, which has been contemplated for some time by the Academy of Medicine of Cleveland. The building was occupied by the Huron Road Hospital for several years. The project will be administered by a nonprofit corporation to be known as "The Cleveland Museum of Health and Hygiene, Inc.," of which the incorporators are Dr. Howard Lester Taylor, Dr. Hubert C. King, Dr. James A. Doull, Mr. Howard W. Green and Mr. H. Van Y. Caldwell, executive secretary of the academy of medicine. The gift was made with two provisos, one that sufficient funds be raised to maintain the museum and that, if the association ceases to function, the property will revert to Mrs. Prentiss.

**Personal.**—Dr. Lorne W. Yule, superintendent of the Institution for the Feeble-minded, Apple Creek, has resigned because of ill health.—Dr. William E. Hudson, New Philadelphia, has been appointed superintendent of a new county sanatorium for tuberculosis shortly to be opened in Tuscarawas County, it is reported.—Dr. Carl J. Wiggers, professor of physiology, Western Reserve University School of Medicine, Cleveland, is on sabbatical leave and with Mrs. Wiggers sailed January 23 for a trip around the world.—Dr. Jesse F. Bateman, Cincinnati, assistant superintendent and clinical director of Longview State Hospital, has been appointed superintendent of Columbus State Hospital to succeed the late Dr. William H. Pritchard.—Dr. John J. Sutter, Lima, who served for many years as health officer of Allen County, was appointed health officer of Wayne County recently to succeed Dr. William G. Rhoten, Wooster, who resigned.

## OKLAHOMA

**Bill Introduced.**—S. 108 proposes to require applicants for licenses to practice any form of the healing art, as a condition precedent to their right to examination by their respective professional boards, to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology to be given by a state board of examiners in the basic sciences. This board is to consist of five members, appointed by the governor for staggered five year terms, each member to be a member of the faculty of the University of Oklahoma, Oklahoma Agricultural and Mechanical College, or some other institution of equal rank in the state and no member to be actually engaged in the practice of the healing art or any branch thereof.

## OREGON

**Bill Passed.**—H. 34 has passed the house, proposing to amend the law so as to require, as a condition precedent to the issue of a marriage license, the presentation of a physician's certificate showing that the prospective bride is free from contagious or infectious venereal disease. The law now requires such a certificate from the groom alone.

and patients, since such devices are frequently not marketed in packages. Nothing in the bill requires any such device to be marked so as to show its origin, purpose, potency or manner of use.

Both the Senate and the House bills define cosmetics as substances and preparations intended for cleansing, or altering the appearance of, or promoting the attractiveness of, the person; except that soaps are not to be regarded as cosmetics so long as they are represented as being for cleansing purposes only or make no claim to medicinal or curative qualities. Since soaps represented as having medicinal or curative qualities come clearly within the definition of drugs, any soap for which any such claim is made would seem to come within the scope of the bill as both a drug and as a cosmetic. A poisonous or deleterious substance in a cosmetic is not to be considered as an adulterant within the meaning of the law unless its presence renders the cosmetic injurious to users under the conditions of use as prescribed in the labeling or advertisements, or under such conditions as are customary and usual. In the Senate bill an effort has been made further to protect the maker and dealer in coal tar hair dyes by providing that the prohibition on potentially poisonous or deleterious substances shall not apply to such hair dyes if labeled:

"Caution—This product contains ingredients which may cause skin irritation on certain individuals and a preliminary test according to accompanying directions should first be made. This product must not be used for dyeing the eyelashes or eyebrows."

In appraising the significance of this proposed legislation so far as it relates to cosmetics, the broad statutory definition of the word "cosmetic" must be borne in mind; if soaps are excluded, every preparation intended for cleansing or altering the appearance of the person or promoting its attractiveness is a cosmetic.

The provisions of both the Senate and the House of Representatives bills with respect to the adulteration and misbranding of foods follow more or less conventional lines. Both bills propose that foods fabricated of two or more ingredients for which no definition or standard of identity has been prescribed shall be labeled so as to show the common or usual name of each such ingredient, but the House bill provides that no such disclosure need be made with respect to the ingredients of any proprietary food the ingredients of which have been fully and correctly disclosed to the Secretary of Agriculture, if the disclosure of the ingredients on the label would give to competitors information they could not otherwise obtain.

In the House bill, under the heading "Misbranded Food," are regulations governing the labeling of distilled liquors which seem to imply that requirements as to the labeling of such liquors when used as beverages may be different from the required labeling when used for medicinal purposes. Some distilled and fermented liquors come clearly within the definitions of the term "drug," since they are recognized in the U. S. Pharma-

copeia and in the National Formulary and in any case may be intended for use in the cure, mitigation, treatment or prevention of disease. The requirements of the House bill relate particularly to blended whiskies. They provide, too, that any substance that professes to be or is represented as whisky is to be regarded as misbranded if it contains alcohol derived from any source other than grain.

The provisions in both the Senate and the House bills with respect to advertising fall short of what might reasonably be expected for the promotion of public health and common honesty, but the fact that there is now an entire absence of any law that seems even remotely to control the advertising of foods, drugs, diagnostic, prophylactic and therapeutic devices, and cosmetics, sold in interstate commerce makes welcome even such protection as these bills propose. Fortunately, both bills propose to prohibit any advertisement of any drug or any device, among persons other than the medical profession, that represents it to have any therapeutic effect in the treatment of Bright's disease, cancer, tuberculosis, infantile paralysis, venereal diseases, and heart or vascular diseases.

If either of these bills should be enacted, it will be enforced by the Secretary of Agriculture. The controversies that raged while legislation of this kind was under consideration by the Seventy-Fourth Congress as to whether the advertising provisions of the law should be enforced by the Secretary of Agriculture or by the Federal Trade Commission, which was largely responsible for preventing an agreement between the Senate and the House of Representatives at the time, seems to have been resolved in these bills in favor of the Secretary of Agriculture. Both bills, however, expressly provide that nothing in them shall be construed to impair or diminish the powers of the Federal Trade Commission under existing law. This seems to be a happy solution of the difficulty. Many who appreciate highly the efforts that the Federal Trade Commission has made during years past and is still making to protect the public against fraudulent medicines and quack practices, with the limited legal authority at its command, still cannot help feeling that under the terms of the bills offered last year and under the terms of these bills a more effective enforcement will be possible if, outside of the field of unfair trade competition, enforcement is entrusted to the Secretary of Agriculture. Cooperation between the secretary and the Federal Trade Commission may be taken for granted.

Lengthy but in many respects ineffective hearings on food, drug and cosmetic bills have been given by committees of the Senate and of the House of Representatives, each acting independently of the other, during several recent sessions of Congress. It has been suggested that hearings on the pending bills be given by a joint committee of the two houses. However reasonable that suggestion may seem, it is of course one

ment of any forcible means for the correction of any deformity of the foot; "surgical treatment" as the surgical treatments of the ailments of the human foot, except amputation of the foot or toes, or the use of anesthetics other than local; and "electrical treatment" as the employment of electricity to the foot or leg by means of electrodes, machinery, rays, lamps, vibrators, or any other apparatus operated by electricity. H. 55, to amend the pharmacy practice act, proposes to authorize the board of pharmacy to license persons, not licensed pharmacists, to keep for sale and sell, in original sealed packages only, such emergency drugs, medicines and poisons as the board may from time to time designate. H. 81 proposes to require all applicants for licenses to practice any form of the healing art, as a condition precedent to their right to examination by their respective professional boards, to pass examinations in anatomy, physiology, chemistry, bacteriology and pathology to be given by the state board of examiners in the basic sciences. The board is to consist of five members, appointed by the governor for staggered five year terms. Members of the board are to be selected because of their knowledge of the basic sciences aforesaid. Each member must be a member of the faculty of the University of Wyoming or other institution of learning of equal rank and no member of the board can be actively engaged in the practice of the healing art or any branch thereof.

### GENERAL

**Fraudulent Subscription Agent.**—Charles C. Thomas, Springfield, Ill., publisher of the *American Journal of Roentgenology and Radium Therapy*, wishes to inform the medical profession that H. H. Harvey, who is posing as a representative of that firm, is in no way connected with it. He is not authorized to accept or solicit orders for the *Journal* or any book publications.

**Changes in Status of Licensure.**—The State Board of Medical Education and Licensure of Pennsylvania reports the following action taken at a meeting December 10:

License of Dr. Walter M. Atkinson, Curwensville, revoked because of mental incapacity due to inordinate use of alcoholic liquor.

License of Dr. Isaac S. Diller, North East, Pa., revoked because of conviction of violations of narcotic laws. At the time of the conviction about five years ago, action was postponed on his promise to refrain from practice. Recently he is said to have made an effort to resume practice.

The New York State Board of Medical Examiners reports the following action at a meeting November 20:

License of Dr. Darwin Hecht, whose last known address is 1368 President Street, Brooklyn, revoked because of conviction of a felony.

License of Dr. Abraham Benjamin, whose last known address is 307 East Broadway, New York, revoked because of conviction of a felony. This was an endorsement of a license issued by the state of Michigan.

The Board of Medical Examiners of the State of Oklahoma reported the following action taken at a meeting December 9:

License of Dr. William Walter Hornsby, now of Mansfield, Ark., revoked because of violation of the narcotic laws.

The State Medical Board of the Arkansas Medical Society revoked the licenses of the following at its meeting Nov. 10, 1936:

Dr. James H. Cole, Morrilton, sentenced to serve eighteen months in a federal penitentiary by U. S. District Court.

Dr. Luther Warren Copeland, Trumann, sentenced to serve two years in a federal penitentiary.

Dr. John D. Eddy, Jerusalem, sentenced to serve two years in a federal penitentiary.

Dr. Walter L. Mason, Atkins, sentenced to serve two years in a federal penitentiary.

Dr. Matthias T. Whickam, Blackwell, sentenced to serve eighteen months in a federal penitentiary.

**Clearing Ships at Quarantine by Radio.**—To facilitate the landing of steamship passengers in the port of New York, the U. S. Public Health Service will grant medical clearance to certain classes of regular passenger vessels by radio, effective February 1, according to the *New York Times*. The new radio system of "pratique" or medical clearance was hailed by steamship concerns as a step forward in increasing the convenience of ocean travel, it was stated, and is the most radical alteration of the country's sanitary defenses against the importation of foreign disease and pestilence since the first quarantine station was established in New York Harbor in 1758. The new system was devised and drafted by Dr. Charles V. Akin Jr., Rosebank, S. I. Ships eligible for the new medical clearance include any passenger vessel in regular service between New York and European ports, between the east and west coasts of the United States via the Panama Canal, between New York and the Panama Canal, and between New York and Bermuda and the West Indies. Vessels ineligible for this clearance are cargo vessels, vessels known or suspected of carrying quarantinable disease, vessels from ports where quarantinable disease is known or is suspected to prevail, vessels with commercial shipments of birds of the parrot family and any vessels of the eligible classification that do not carry qualified ship's surgeons familiar with quarantinable

diseases. These surgeons must be certified by the ship owners and by national health authorities where they are registered. Application for radio clearance must be made not more than twenty-four hours or less than twelve hours before its expected arrival at New York to the ship's agents or owners, who in turn get notification from the health station at quarantine. In the event that communicable disease develops on the ship after it has received clearance, the master of the ship must notify the health commissioner and hold victims of the disease in isolation pending disposition as directed by city health officers. Ships that have received clearance by radio will pass right through quarantine and go immediately to their docks. In some cases the abolition of the quarantine delay will save as much as half a day in docking ships.

**Medical Bills in Congress.**—*Changes in Status:* S. Res. 69, creating a Senate Select Committee on Government Organization, has passed the Senate. All bills and resolutions introduced in the Senate proposing legislation concerning reorganization, coordination, consolidation or abolition of units in the executive branch of the government will be referred to this committee. The committee is authorized to report to the Senate at any time by bill or otherwise its recommendations on any matters covered by the resolution. Any bill or resolution so reported is to be accorded a privileged status. H. J. Res. 81 has passed the Senate, with amendment, proposing to create a Joint Committee on Government Organization, with powers to investigate the organization and activities of the various units of the government to determine whether any such units should be coordinated, consolidated or eliminated. S. 115 has passed the Senate, proposing to add the name of Gustaf E. Lambert to those honored by the act recognizing the service rendered by Major Walter Reed in the discovery of the cause and means of transmission of yellow fever. *Bills Introduced:* H. R. 2714, introduced by Representative Tolan, California, proposes to provide employment for the blind citizens of the United States and its possessions. H. R. 3589, introduced by Representative Colmer, Mississippi, proposes to extend to contract veterinarians the benefits accorded veterans of the Spanish-American War, including the Philippine Insurrection and the China Relief Expedition. H. R. 3676, introduced by Representative Dowell, Iowa, proposes to erect a three hundred bed addition to the veterans' hospital at Des Moines, Iowa, for the treatment of general medical and surgical disabilities. H. R. 3680, introduced by Representative Pfeifer, New York, proposes to amend the Social Security Act by authorizing an appropriation of \$25,000,000 to assist states, counties, health districts, and other political subdivisions of the states in the control of venereal diseases. H. R. 3796, introduced by Representative Kvale, Minnesota, proposes to extend the privileges of compensation and hospitalization accorded to members of the American military forces to American citizens who volunteered in the French military forces and while serving in the Foreign Legion or while serving in flying status in the Lafayette Escadrille or Lafayette Flying Corps, received injuries of a permanent nature of more than a 10 per cent degree in line of duty between the dates of April 6, 1917, and Nov. 11, 1918.

## Government Services

### Pennsylvania Accredited for Tuberculosis Eradication

Federal recognition of Pennsylvania as a modified accredited area, the state having reduced bovine tuberculosis to less than 0.5 per cent, was celebrated with special ceremonies at Harrisburg, December 16. Forty-three states have now been accredited.

### Government Builds Second Narcotic Farm

The cornerstone of the United States Narcotic Farm will be laid at Fort Worth, Texas, February 13. Speakers at the ceremonies will include Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, and Miss Josephine Roche, Assistant Secretary of the Treasury, Washington, D. C. This is the second narcotic farm to be built by the U. S. Public Health Service under the jurisdiction of the division of mental hygiene. The first was opened in May 1935 at Lexington, Ky. During the first year the Lexington institution admitted 1,240 persons as patients. Of this number 283 were voluntary patients. According to the annual report of the public health service "there is no question that the treatment of narcotic addiction in a hospital has distinct advantages over the management of such cases in a correctional institution."

prohibition experiment, and the publicity was both misdirected and too concentrated. These mistakes must not be made again.

The Advisory Committee to the United States Public Health Service has recognized that there would be difficulties facing the educational campaign. "It is recognized," said the committee, "that much may be done to improve this material and to direct it more specifically to the people in need of advice. It would be of great assistance if the Public Health Service were to carry out a thorough study of public health educational programs and methods. Such a study should include the usefulness of the radio, the press, motion pictures, pamphlets and posters, lectures, exhibits, and other methods in the educational program. There is now a wealth of practical experience in the use of these media in general, but little accurate knowledge of the principles, practices and results of popular education pertaining to the venereal diseases." This study should be conducted by recognized experts in the field of publicity. Pending the result of such a study, it would be well if the publicity campaign could be more closely guided by the two most competent and appropriate medical agencies, the American Medical Association and the U. S. Public Health Service. The foundations must be built slowly, accurately and firmly. This will prevent the development of a shaky superstructure that will collapse under our feet.

## Current Comment

---

### CALCIUM AND IRON IN BLOOD FORMATION

Many of the life processes of the organism are known to be the resultants of integrated chemical reactions. The student of comparative biochemistry is likely to view these as results of the adaptations whereby evolution has taken place. Thus the orderly oxidation of fat in the body ordinarily requires the concomitant combustion of carbohydrate; the utilization of iron seems to depend, in part, on the presence of copper; the efficiency of the respiratory pigment is conditioned by the presence of inorganic salts and, without free hydrochloric acid, peptic digestion does not proceed normally. With further investigation, more relationships of this sort will be uncovered. A recent study by Orten, Smith and Mendel<sup>1</sup> has emphasized the close relationship between calcium and iron in the formation of erythrocytes and hemoglobin. With the albino rat as the experimental animal, it was shown that the characteristic and abnormal blood picture resulting from a severe restriction of inorganic salts in the food could be changed toward the normal condition by adding only calcium to the diet; likewise growth, which had ceased on the deficient ration, was resumed without the caloric intake being increased. The addition of iron at this stage was essentially without effect. If, however, iron alone was added to the salt-poor experimental ration

at the outset, it exerted a favorable effect on the blood cells for a time, apparently, according to the authors, until the available store of calcium in the skeleton had been depleted. Clinical experience abounds with instances of a close correlation between these two important elements. Frequently deficient hematopoiesis is attributed to the untoward alteration of the structure of the bone resulting from faulty calcium metabolism; a chemical explanation, as herein suggested, may not infrequently be more tenable.

---

### NASAL VENTILATION IN CONTROL OF HEADACHE

One of the problems often confronting the practicing physician, according to Parkinson,<sup>1</sup> is that of long standing recurrent headache. In a proportion of the cases one can determine quickly and with considerable accuracy, he believes, whether a headache is or is not of local origin by noting the effect of thorough ventilation of the nose and the sinuses. "Local origin" he defines as arising from a known cause such as undue positive or negative pressure within a sinus or contact pressure of swollen intranasal structures. Obviously, a negative effect from ventilation is not as diagnostically reliable as a positive effect. Shrinkage of the nasal mucosa and displacement of ephedrine solution into the sinus ordinarily are easily and quickly carried out. The "lateral head-low posture" is, Parkinson believes, adequate for this purpose, because it is based on the anatomy of the region. It has the advantages of simplicity and directness and can be carried out entirely without discomfort and with little trauma. The posture mentioned has been shown to make available for displacement simultaneously all the sinuses of one side or of both sides, unless they are barred by hyperplasia or by other unshrinkable tissue. This seems like a useful and safe method of diagnosis and control of headache due to abnormalities of pressure in the accessory sinuses.

---

### DICTAPHONE DUST DERMATITIS

The list of substances alleged to produce dermatitis in sensitized persons continues to increase. One of the most recent additions to the group of offending agents is dust from dictaphone cylinders.<sup>1</sup> Apparently, this is the first description of dermatitis from such a source. The subject was a man, aged 54, who was employed in a large business office in which dictaphones were used. Since the installation of the machines, about eight years ago, he had experienced intermittent attacks of dermatitis affecting the face, the back of the hands and the ankles. He had observed that his skin cleared and remained normal during a period of five months when he had been away from the office—and dictaphones. Recurrences invariably followed contact with the machines. The patient was requested to secure some dictaphone dust as well as scrapings from the composi-

cated in the country, my early boyhood was spent in the pleasant pursuit of studying animal life in fields, lanes, ditches, ponds and hedges." He began to train for a schoolmaster, but his interest in natural history decided him to become a surgeon. In 1878, at the unusually late age of 23, he joined the Middlesex Hospital School of Medicine, but he lost no time and qualified in 1882 and gained the F.R.C.S. six years later. At the school he won a scholarship and gold medals and came under the notice of the anatomist and distinguished surgeon Mr. Henry Morris, who made him a prosector. In 1881 he was appointed demonstrator of anatomy, and his interest in comparative anatomy and pathology led to his joining the prosectorium of the Zoological Gardens. He contributed valuable papers on these subjects to the *Proceedings of the Zoological Society* and the medical journals. He described the Zoological Gardens as "a rich hunting ground for pathological spoil" and in 1886 was able to write "Since 1878 I have systematically examined the bodies of 12,000 animals from fish up to man." This work gave great breadth to his knowledge of disease. With a philosophic mind stored with facts drawn from many sources, a keen scientific imagination and a simple and lucid style, he became a fascinating teacher with tongue and pen. Take this reflection on his work at the Zoological Gardens: "My attention has always been aroused by two very opposite conditions—the paucity and, in some cases, the absence of lesions to account for death; in the other case, by extensive disease of vital organs which must have been present for a considerable time without destroying life." Referring to the theory that in the human species the erect posture is responsible for prolapse of the uterus, he pointed out that this occurred with tolerable frequency not only in domesticated mammals but in the lioness, the deer, the antelope and other animals. Similarly he found flexion of the uterus in greater degree in monkeys than in women. He concluded that there must be other causes for these conditions than the erect posture.

In 1886 he was appointed assistant surgeon to the Middlesex Hospital and in 1891 surgeon to the Chelsea Hospital for Women. He devoted himself mainly to the surgical treatment of the diseases of women, a subject in which he was one of the pioneers. Before his time gynecology was in the hands of physicians who specialized in the subject before the antiseptic system made abdominal surgery possible. He was good at diagnosis and a rapid and skilful operator. He wrote and lectured extensively. A fluent speaker, he kept his audience on the alert by quips, unexpected examples drawn from the animal kingdom and homely but telling modes of expression sometimes drawn from the Bible. In dealing with clinical subjects he had the advantage of a foundation in pathology such as no one could claim. Among subjects with which he was particularly identified were the treatment of uterine myomas, pregnancy complicated by tumors, the after-effects of operations on the female pelvic organs, and gallstones. He was the greatest authority of his day on tumors, on which his book remained the standard one for thirty years. His interest in animal life led him to travel all over the world. He always brought back new facts which he turned to good account in his writings. In Spain the bull ring attracted him and he explained how the various steps were designed to weaken the muscles of the bull's neck and finally to bring him into such a position that the matador could use the espada with deadly effect. At the Royal College of Surgeons he was Erasmus Wilson lecturer (1885-1887), Hunterian professor of comparative anatomy and surgery (1887-1889), Bradshaw lecturer (1918), Hunterian orator (1923) and president (1923-1925). He was the first president of the Association of Surgeons of Great Britain and Ireland (which was founded in 1918, mainly by the efforts of Lord Moynihan), president of the Medical Society of London (1914) and president of the Royal Society of Medicine (1920). He was appointed by the war office to

collect the large number of specimens of gunshot injuries of the great war. The collection, with valuable clinical histories, is now housed at the Royal College of Surgeons.

In addition to numerous papers, the following are his most important books and contributions to books: "Comparative Dental Pathology," "An Introduction to Pathology" (based on three Erasmus Wilson lectures delivered at the Royal College of Surgeons), "Comparative Dental Pathology," "Ligaments Their Nature and Morphology," "Dermoids," "Surgical Diseases of the Ovaries and Tubes," "Tumors Innocent and Malignant," "Tumors and Diseases of the Jaw," "Osteology" in Morris's "Anatomy," "Essays on Hysterectomy," "Diseases of Women" (with A. E. Giles), "Gallstones and Diseases of the Bile Ducts," "Tumors" in Keen's Surgery and also in Warren and Gould's International Textbook of Surgery, "Fibroids," "Misplaced and Missing Organs," "Man and Beast in Eastern Ethiopia" and "Man and Creatures in Uganda."

Jan. 2, 1937.

### Obligatory Retirement of Medical Teachers

The Pomaret bill, which will propose the surrender of the diploma and licenses to practice not only of physicians and dentists but also of members of all liberal professions, such as architects and engineers, at the age of 65, is scheduled to be debated in the national legislature. The fight against passage of such a law has been so well organized by the medical and dental professions in France that the chief sponsor of the bill, Mr. Pomaret, has been quoted as seeing the injustice of forcing professional men to retire at the age of 65 without any compensation in the form of a government pension. The object of the sponsors of the proposed law was to relieve the congestion in the liberal professions, thus permitting recent graduates to make more rapid progress than if the higher positions were occupied by their predecessors. The opposition to the bill has assumed formidable proportions, and at present it is doubtful whether the bill will be pushed. A severe blow in a similar direction has, however, been delivered as the result of the passage of a recent law according to which professors in the medical schools will be obliged to retire at the age of 65 instead of 70 as is at present the case in France. Professors in the Institute of France, who are appointed because of their research or other contributions to the progress of the arts, will be obliged to retire at the age of 55. This law has as one of its immediate results the obligatory retirement of four of the leading teachers in the Paris Medical School, including the cardiologist Laubry, who was recently elected to this chair. Another recent law would not permit any one who has retired on a government pension after reaching the age limit to add to his income by occupying any public office or the pursuit of any business or profession. This law would apply equally to those engaged in teaching in a public institution during a portion of their time and would prevent them from accepting compensation for work done outside such a position. These socialistic proposals have aroused such a storm of indignation, including the minister of public instruction, that their enforcement has been temporarily suspended.

### Medical Control of Sickness Claims in Social Insurance

Collusion between unscrupulous physicians and the insured necessitates constant supervision, through its medical inspectors, by the disbursing bureaus of the social insurance organization. A case was referred to, in a recent letter, in which such collusion had taken place. The physician was fined and given a short jail sentence. At a recent meeting of the Associated Disbursing Bureaus, Dr. Forestier of Paris outlined how medi-

are recurrent proposes to authorize the sterilization also of inmates who are afflicted with epilepsy, or incurable primary or secondary types of feeble-mindedness.

### IOWA

**Bill Introduced.**—S. 24, to amend the workmen's compensation act, proposes to make the employer liable to furnish and pay for the surgical, medical, nursing and hospital services necessary to treat an injured employee, without limit as to time or amount.

### KENTUCKY

**Louisville Quarantined.**—Strict quarantine on the west end of Louisville, the most deeply flooded area of the city, and a modified quarantine in an area extending five miles beyond the city limits on every highway entering the city were imposed by the state board of health effective February 1 to keep down epidemics in the wake of the flood. More than 125,000 persons had received inoculations for typhoid up to January 30, and 20,000 a day were continuing to receive them. Materials for 10,000 smallpox vaccinations have also been distributed. The U. S. Public Health Service is installing typing services for pneumonia serum, and an emergency hospital with operating rooms and oxygen tents has been set up in a city high school. Dr. Robert Olesen with a group of sanitary engineers and chemists of the U. S. Public Health Service, six biologists and chemists of the New York City Department of Health and representatives of the Tennessee Valley Authority were among those who went to aid Louisville in its fight against disease. Regulations have been issued for the reoccupation of the evacuated homes, warning especially that "the occupation of damp houses, especially by children and aged persons, is conducive to respiratory ailments, rheumatic disorders and greatly reduced resistance to other illnesses."

### MAINE

**Personal.**—Dr. Herbert R. Kobes, Augusta, has been placed in charge of the maternal and child health program now being carried out by the state department of health with social security funds.

**Society News.**—Dr. Edwin H. Place, Boston, addressed the Cumberland County Medical Society in Portland, December 11, on "Prophylaxis of Contagious Diseases."—At a meeting of the Hancock County Medical Society in Ellsworth, December 16, the speakers were Drs. Raymond Van Ness Bliss, Blue Hill, on "Chronic Lead Poisoning" and Raymond E. Weymouth, Bar Harbor, "Dextrose as a Therapeutic Agent."—The speakers before the Kennebec County Medical Association in Augusta, December 17, included Drs. Howard F. Hill, Waterville; Arch H. Morrell, Augusta, and Charles B. Popplestone, Rockland, who presented a symposium on syphilis. Dr. Harold G. Tobey, Boston, addressed the Penobscot County Medical Association, December 15, on "Acute Upper Respiratory Infections." Dr. Frederick T. Hill, Waterville, president of the state association, also spoke.—Dr. Jacob Schloss, Boston, discussed "Coma in Diabetes" before the Oxford County Medical Association and members of the staff of the Rumford Community Hospital, December 17.

### MASSACHUSETTS

**Psychiatric Awards.**—The New England Society of Psychiatry at its next spring meeting will make two awards, one of \$50 and one of \$25, to the writer of the best papers completed or published during the calendar year 1936, embodying research in psychiatry by a younger worker. Physicians, psychologists, social workers or others are eligible and membership in the society is not a requisite. Writers who have once received the award are not again eligible. Seasoned writers, senior physicians, or heads of departments in which there are junior workers, while not inevitably excluded, will not generally be regarded as eligible for the awards. The work on which the papers are based should preferably have been done in New England or by workers now living in New England. Copies of articles or marked copies of journals in which the articles appeared should be sent before March 1 to the secretary of the society, Dr. Harlan L. Paine, North Grafton, Mass.

**Bills Introduced.**—S. 136 proposes to authorize the establishment and maintenance, within either Essex or Middlesex County, of an institution for the care and treatment of persons who reside within said counties and are suffering from cancer. S. 194 proposes to establish an independent board of registration in "chiropody (podiatry)" and to regulate the practice of that calling. The bill defines chiropody (podiatry) as "the external treatment of the structures of the human foot

by medical, mechanical or surgical means without the use of other than local anaesthetics." The board of registration in chiropody (podiatry) is to consist of four chiropodists and one licensed physician. H. 720 proposes that in all proceedings for the discharge of a person from an institution for the insane the person shall have the right to be examined, at his own expense, by physicians of his own choice so as to enable them to testify in such proceedings. H. 724 proposes a new workmen's compensation act. Among other things, the bill proposes that, from the date a worker is injured, he shall be furnished, free of charge to himself, adequate and reasonable medical, hospital and nursing services without limit as to time or amount, and the injured worker is to be permitted to designate the physician, nurse or hospital to care for him. H. 1060 proposes to establish a commission, to consist of one senator, three representatives and one person appointed by the governor, to investigate and study physical therapy, electro-physiology, electrotherapeutics and hydrotherapeutic technic. This commission is to investigate and study anatomy, physiology, analysis of muscle and joint motion and scientific massage and to report to the general court the results of its investigations, with recommendations, before the first Wednesday of December 1937. H. 1150 proposes to repeal the compulsory vaccination law and to provide that no person shall be required to submit to any form of vaccination or inoculation as a condition precedent to admission to any public institution of learning or to the exercise of any right, performance of any duty or enjoyment of any privilege. The bill proposes also that any physician who vaccinates an adult under guardianship or a child, without the written consent of the parent of such child or the guardian of such adult, shall be subject to a fine of \$100 or imprisonment for one year or both. H. 1151 proposes to require whoever attends, treats or is called to attend a case of induced abortion to report such case at once to the police authorities and to the appropriate medical examiner. If such a case is treated in a hospital, the superintendent or other person in charge thereof is required to make the indicated report. H. 1255, to supplement the workmen's compensation act, proposes that an injured employee shall select a physician to treat him from a list of physicians established by the department of industrial accidents. H. 1425 proposes that an applicant for a license to operate a motor vehicle furnish a certificate executed on the basis of a medical examination, showing that the applicant is physically and mentally fit and has a favorable intelligence rating.

### MINNESOTA

**Bill Introduced.**—S. 163 proposes a new optometry practice act. It defines "optometry and the practice of the profession of optometry" as "the employment of any objective or subjective means or methods for the examination, diagnosis and determination of any optical defects, deficiencies or deformities of the refractive powers of the human eye, or any visual or muscular anomalies thereof, and the prescribing or adapting of lenses, prisms, ocular exercises or any means for its correction, aid or relief thereof." The bill proposes to make it unlawful for any person not duly licensed as an optometrist to practice optometry as just defined but provides that nothing contained therein "shall be construed as prohibiting any person duly licensed to practice any profession in this state from practicing his profession under the laws of this State relative thereto." Possibly this may be construed to prevent licensed physicians from fitting eyeglasses and spectacles.

### MISSISSIPPI

**Dr. Dye Is Mayor of Clarksdale.**—Dr. Thomas M. Dye is now mayor of Clarksdale, in Coahoma County, according to the *Mississippi Doctor*. He has been secretary of the state medical association since 1917. Clarksdale has a population of 10,043.

**New Health Unit.**—A new health unit was placed in operation in Jones County January 1, with Dr. Alton R. Perry, Natchez, formerly health officer of Adams County, in charge. Dr. Charles R. Gillespie, formerly of Greenwood, acting director of Leflore County, will succeed Dr. Perry in Adams County.

**Society News.**—The East Mississippi Medical Society was addressed in Meridian, December 10, by Drs. Eugene B. Vickery, New Orleans, on "Present Day Diagnosis and Treatment of Renal Tumors"; Ray L. Rhymes Jr., Meridian, "Pediatric Surgery"; Charles F. Craig, New Orleans, "Amebiasis," and Seale Harris Jr., Birmingham, Ala., "Treatment of Cardiovascular Syphilis."—Dr. John T. Sanders, New Orleans, discussed "Diagnosis and Treatment of Carcinoma of the Uterus and Cervix" before the Tri-County Medical Society in Brookhaven, December 8.

Standards applied to individual young persons before aid is granted are political and moral reliability, scholarly capability and economic want. Assistance may take the form of a loan scheduled to mature within from one to five years or a monthly stipend may be granted. In this way the youthful graduates are assured a minimum income on which to subsist as well as the possibility of marriage. The funds are supplied from the treasury of the German Docents' Society and by the National Federation of German Universities. The latter organization has only just been disbanded. The self-help activities are to be subsidized in future by voluntary contributions. The exact rates of contribution have been established by the National Ministry of Public Instruction and they are so scaled that any one kindly disposed toward the cause may contribute his bit. This means a sacrifice on the part of some persons but in the interest of the greater number. Along with the financial aid there shall be an equitable distribution under supervision of the Reichsdozentenwerk of the available assistantships and other posts.

A comparison of the foregoing with the data on the "condition of the brain workers," which recently appeared in *Soziale Praxis*, is of particular interest. The total number of such workers is reckoned at around 608,000; this group is distributed professionally, 265,000 in technical-scientific fields, 142,000 in the arts, 99,000 in education and 102,000 in other fields of intellectual endeavor. There are in Germany today about 36,000 architects, 211,000 engineers, 13,000 chemists, 51,000 physicians, 12,000 dental physicians, 48,000 teachers of special subjects, 19,000 attorneys and 17,000 publicists. In the year 1933 there were registered at the employment offices 93,000 unemployed brain workers; by 1936 this number had been reduced to 28,500.

The retrogression in the number of the unemployed has been especially marked in the technical professions; there were in June of this year only about 7,000 unemployed technicians. In addition to this favorable outlook for the engineers there has been an increased demand for physicians. Little improvement is apparent in the condition of the legal profession; statistics show that even now 41 per cent of its members earn less than 3,000 marks yearly. Women teachers too are in a bad way. Men teachers fare slightly better despite the overcrowding in the teaching field. In 1933 there were about 29,000 unemployed artists; during the current year this number had sunk to somewhat below 19,000. Whereas 43,600 persons completed the secondary schools in 1933, only 25,850 had done so in 1936. In the summer semester of 1932 there were 18,300 new matriculants in the universities; for the winter semester 1935-1936 the corresponding figure was 9,100 matriculants, and for the summer semester of 1936 only 5,500.

## BUCHAREST

(From Our Regular Correspondent)

Dec. 4, 1936.

### Four Thousand Cases of Pellagra in One County

In the county of Gorj, 4,000 cases of pellagra have occurred in the last two months. A committee sent to this district to investigate established that the probable cause of the epidemic is the consumption of unripe maize. In this district bread is made from maize flour mixed with wheat flour, the ratio being 3:1. But maize flour is used also in cooked form. The popular dish of the peasants, called mamaliga, is made from maize flour and milk and a little cheese. While the disease generally makes its appearance during the spring months, in this case it occurred in the late summer and early fall. Another striking feature is the acute character of the onset. The rashes on the hands and feet are very painful. The county health officer hastened to the help of the unfortunate patients by distributing

large quantities of wholesome wheat flour and preparations containing vitamins. Severely affected persons were taken to hospitals, while the less severely affected were treated in their homes. Since this intervention no new cases have occurred.

### Marriage of Leprous Patients in the Rumanian Leper Camp

In the district of the Danube delta there are a number of lepers for whom the state erected a camp on the border of the village of Tichilesti, where they are kept under strict medical supervision. There are men and women of all social classes. Recently two couples appealed to the camp physician for permission to marry. In one instance a man of 26 wanted to marry a woman of 26. In the other instance a man of 36 asked the hand of a 16 year old girl. As the law does not forbid the intermarriage of leprosy patients, the doctor had to give his consent, explaining that the couples would have to remain in the camp all their life. An improvised altar was put up on the meadow adjacent to the village, and a clergyman and a registrar appeared in white coats and leather gloves; the parties did not write their signatures into the registry book, as is customary. After the short ceremony the newly married couples returned to the camp and the clergyman, the registrar and the physicians burned their white cloaks, gloves and shoes and fumigated all the witnesses.

### National Congress on Contagious Diseases

The first Rumanian Congress on Contagious Diseases was held in Craiova. M. Costinescu, minister of health, presided and all the counties of Rumania sent official delegates. Dr. Costinescu, minister of health, said that the child mortality rate in Rumania is the highest in Europe. The cause is contagious diseases. Far reaching public health innovations are necessary to check the ravages of contagious diseases. Public health organizations have to be extended to the most remote villages. Dr. Viorel Popescu emphasized the necessity of holding graduate courses to make the prophylaxis of contagious diseases more efficacious. He showed that in the rural districts the mortality rate due to contagious diseases is three times that in towns. The cause of this is neglect of the villages. At present, one physician has under his care usually thirty villages, or 20,000 to 30,000 persons. The position of the village physicians is aggravated by the small salary given them. Dr. Anastaziu urged the erection of more hospitals for contagious diseases in the rural districts, rendering possible the segregation of infectious patients. In his opinion it is the duty of the health ministry to insure that at most 10,000 persons shall have one physician, every 3,000 inhabitants shall have one relief station and every 2,000 souls shall have one nurse. The doctor and his staff shall dwell at the seat of the relief station and at the same place shall be an infirmary for epidemic cases and also an ambulance.

### The Bust of Professor Babes

A bust of the late Professor Babes, founder of the first Pasteur institute in Bucharest, was unveiled in Bucharest October 27. The bust is placed in a beautiful square, opposite the Bucharest Bacteriologic Institute. Memorial addresses were made by Professors Bacalogliu, Ciuca, Manicatide, Marinescu and Proca. At the same time the remains of Professor Babes were interred in the crypt situated in the garden of the bacteriologic institute. He died ten years ago and was buried in the Bucharest Greek Catholic cemetery.

### Meeting of the Balkan Medical Union

The Congress of the Balkan Medical Union was held this year in Istanbul, Turkey, October 7-13, and it was attended by about 200 members, chiefly from Turkey, Rumania, Yugoslavia and Greece. The main topic of discussion was the position of

**Society News.**—Dr. Charles H. Manlove, Portland, addressed the Klamath and Lake county medical societies at a special meeting, January 13, on the etiology of polycystic kidneys.—The Alumni Association of the University of Oregon Medical School will hold its next meeting March 8-10 in Portland, celebrating the fiftieth anniversary of the founding of the medical school.—Dr. Louis P. Gambee, Portland, addressed the Central Willamette Medical Society, Eugene, December 3, on intestinal obstruction.

### PENNSYLVANIA

**Bill Introduced.**—H. 255 proposes to create a chiropractic board of examination and licensure in the department of public instruction and to regulate the practice of chiropractic. Chiropractic is defined as "the examination of the human spine by observation, palpation or x-ray and the adjustment of any or all misalignments of vertebrae or adjacent bones or tissues through the use of the hands."

**Pneumonia and Venereal Disease Control Commissions Appointed.**—Dr. Maxwell Lick, Erie, president of the Medical Society of the State of Pennsylvania, has appointed a commission for the study of pneumonia control in accordance with action of the society's house of delegates at the 1936 meeting. Members are Drs. Edward L. Bortz, Philadelphia, chairman; Edward W. Bixby, Wilkes-Barre; George J. Kastlin and Clifford C. Hartman, Pittsburgh; T. Grier Miller, Henry K. Mohler and Leon H. Collins Jr., Philadelphia; Clifford W. Skinner, Meadville, and Mathew H. Sherman, Harrisburg. Dr. Lick has also appointed a commission on the control of syphilis and venereal diseases with the following members: Drs. Robert L. Gilman, Philadelphia, chairman; Daniel P. Ray, Johnstown; William B. Washabaugh, Erie; Francis M. Ginley, Scranton; Harold L. Mitchell, Pittsburgh, and James M. Henninger, Woodville.

### Philadelphia

**Death of Mr. Blakiston.**—Mr. Kenneth Mackenzie Blakiston, president of the publishing firm of P. Blakiston's Son & Company since 1898, died January 19, aged 77. Mr. Blakiston was connected with the firm for more than sixty years.

**Faculty Changes at Temple.**—Dr. Thomas Klein has been appointed professor of clinical medicine and Dr. Sherman F. Gilpin clinical professor of neurology at Temple University School of Medicine, it was recently announced. Promotions announced include the following:

Dr. Samuel B. Hadden, to be clinical professor of neurology.  
Dr. Edwin Sartain Gault, associate professor of pathology and bacteriology.  
Dr. Harry E. Bacon, assistant professor of proctology.  
Dr. Daniel J. Donnelly, assistant professor of medicine.

**University Alumni Honored.**—At Founder's Day exercises at the University of Pennsylvania, January 23, in tribute to the memory of Benjamin Franklin, Drs. George E. de Schweinitz, emeritus professor of ophthalmology, and Robert Tait McKenzie, sculptor and research professor of physical education, were among six alumni who received awards of merit. The citations, inscribed on scrolls, were presented by Luther Martin, New York, president of the General Alumni Society, which sponsored the exercises. Dr. Arthur Bruce Gill was elected director-at-large of the society.

### UTAH

**Bills Introduced.**—H. 48 proposes that all "registered physicians and surgeons recognized by the laws of the state of Utah" shall have equal privileges in treating patients in tax free hospitals. H. 55 proposes to require applicants for licenses to practice any form of the healing art, as a condition precedent to their right to be examined by their respective professional committees, to pass examinations in anatomy, physiology, pathology, bacteriology and chemistry so far as they relate to the human body or mind. Such examinations are to be given by a committee of basic science examiners, to consist of five members, all of whom must be full-time, paid professors or associate or assistant professors teaching all or part of the basic sciences enumerated and none of whom may be actively engaged in the practice of the healing art. S. 58, to amend the workmen's compensation act, proposes to add to the list of compensable occupational diseases "poisoning by benzol or nitro-hydro, hydroxy-, and amido-derivatives of benzene (dinitro-benzol, anilin, and others) or its sequelae; poisoning by carbon bisulfide or its sequelae, or any sulfide; poisoning by nitrous fumes or its sequelae; poisoning by nickel carbonyl or its sequelae."

**Report of Committee on Syphilis.**—The Utah State Medical Association recently appointed a committee to cooperate with the state board of health in a campaign against syphilis

and other venereal diseases. The committee has made a preliminary report. Among the recommendations are (1) that the state board of health furnish blank forms to physicians for reports of cases, (2) that the state furnish antisyphilitic drugs free to physicians for indigent patients and those with small incomes and (3) that physicians agree to charge patients of moderate incomes \$2 for administering intravenous drugs and \$1 for administering intramuscular drugs. The committee also recommended that Wassermann tests on pregnant women be made compulsory and that prenuptial Wassermann tests be popularized through education. To help educate the public the committee suggested that the association and the board of health appeal to physicians to disseminate information to their patients, that a group of speakers be prepared to address medical and lay assemblies, and that a full time specially prepared man be detailed from the U. S. Public Health Service to direct this work. Use of the radio, newspapers and educational institutions to help spread information was recommended. Dr. Edward S. Pomeroy is chairman of the committee, and members are Drs. John U. Giesy, Richard P. Middleton, Francis A. Goeltz, Walter G. A. Schulte, Clifford J. Pearsall and Legrand Woolley, all of Salt Lake City.

### VERMONT

**Personal.**—At the recent annual meeting of the Vermont State Medical Society Dr. James N. Jenne, Burlington, resigned from the medicolegal committee after a membership of twenty-five years.

**Bill Introduced.**—H. 23, to amend the medical practice act, proposes (1) to provide that five, instead of four, members of the board of medical examiners be nonsectarian physicians and that two members be homeopaths; (2) to eliminate the present requirement that one board member be an eclectic physician; (3) to authorize the board, in its discretion, to refuse to license applicants who are graduates of foreign universities or medical schools unless their credentials have first been passed on by the national board of medical examiners or by the Council on Medical Education of the American Medical Association; (4) to require that applicants to be licensed must pass written examinations in the subjects enumerated, with an average grade of 75, with not less than 60 in any one subject, examinations in materia medica being conducted by members of the board representing the same school as the applicant, if the applicant so requests; (5) to add gynecology to the list of subjects in which applicants are examined, and (6) to exclude from the operation of the act "the domestic administration of family remedies."

### WASHINGTON

**Bill Introduced.**—S. 62 proposes to authorize the director of licenses to appoint an examining committee in naturopathy and to regulate the practice of naturopathy. The bill nowhere attempts to define such practice or to state the scope of such a license. It provides, however, that "the intent of this act is to establish naturopathy in the state of Washington as a complete system of therapeutics consistent with the basic philosophy as recognized by the Washington State Naturopathic Association." Apparently an applicant for such a license must pass examinations in the basic sciences to be given by the examining committee in the basic sciences before the proposed naturopathic committee may examine or license him.

### WISCONSIN

**Bill Introduced.**—A. 19 proposes to prohibit any agent of a relief agency, employer, agent of an employer, or agent of an insurance company from influencing, inducing or persuading, or attempting to influence, induce or persuade, an injured or sick person to engage any particular physician or surgeon or to change from a physician or surgeon engaged for attendance on him to another. The bill, however, is not to apply "to life insurance companies in any county where a county physician is employed continuously or in any city where a city physician is employed continuously."

### WYOMING

**Bills Introduced.**—H. 27 proposes to create a board of chiropodist examiners and to regulate the practice of chiropody. The bill proposes to define "a chiropodist, also called a podiatrist . . . as one who for hire, or reward, examines, diagnoses, or treats medically, mechanically, surgically, or by electrical and manipulative means, or by bandaging and strapping the ailments of the human foot." The bill further proposes to define "medical treatment" as the local application or recommendation of any therapeutic agent or remedy for the relief of foot ailments; "mechanical treatment" as the employ-

## Deaths

**William Guilford Stearns** \* Chicago; Northwestern University Medical School, Chicago, 1893; professor of pathological anatomy and general pathology at the Northwestern University Dental School, 1894-1898, and assistant professor of mental diseases and medical jurisprudence at his alma mater, 1898-1900; lecturer of neurology at the College of Physicians and Surgeons, 1900-1902; fellow of the American College of Physicians; member of the American Psychiatric Association and the Central Neuropsychiatric Association; chairman of the section on insanity of the National Conference of Charities and Correction in 1898; served with the Medical Advisory Board No. 3E, Selective Service, as a consultant in neuropsychiatry, 1917-1919; assistant physician to the Illinois Eastern Hospital for the Insane, Kankakee, Ill., 1894-1895, pathologist, 1895-1897, and medical superintendent, 1897-1899; medical superintendent of the Oakwood and Lakeside Sanatoria, Lake Geneva, 1900-1904; medical director of the North Shore Health Resort, Winnetka, Ill., 1931-1936; aged 71; died, January 11, at his home in Evanston, Ill.

**Ernest Ellsworth Laubaugh** \* Boise, Idaho; Medico-Chirurgical College of Philadelphia, 1909; fellow of the American College of Physicians; formerly secretary of the Idaho State Medical Association; assistant demonstrator of physical diagnosis at his alma mater, 1911-1912, and assistant in the department of neurology, 1912-1913; bacteriologist to the state board of health, 1913-1917, and medical advisor to the department of public welfare, 1919-1920; served during the World War; director of laboratories, St. Luke's Hospital; chief of laboratory service, St. Alphonsus Hospital; formerly director of the clinical laboratory, Veterans Administration Facility; aged 49; died, Dec. 13, 1936, of pneumonia.

**Oscar Edwin Locken** \* Crookston, Minn.; University of Minnesota Medical School, Minneapolis, 1920; speaker of the House of Delegates of the Minnesota State Medical Association; first vice president and member of the executive committee of the Minnesota Public Health Association; formerly mayor of Crookston; at one time health officer of Crookston; past president of the Minnesota Sanitary Conference, Red River Valley Medical Society and the Minnesota League of Municipalities; president of the Sunnyston Sanatorium Commission; member of the state planning board; on the staff of the Bethesda and St. Vincent's hospitals; aged 45; died, January 18, of pneumonia.

**Herman Schwatt** \* Spivak, Colo.; University of Pennsylvania Department of Medicine, Philadelphia, 1906; past president of the Denver Sanatorium Association; medical director and superintendent of the Sanatorium of the Jewish Consumptives' Relief Society; formerly medical director of the Workmen's Circle Sanatorium, Liberty, on the staffs of the Montefiore Hospital, New York, Montefiore Hospital Country Sanatorium, Bedford Hills, and St. Joseph's Hospital for Consumptives, New York; aged 58; died, January 7, in the Beth Israel Hospital, Denver, of influenza.

**Lewis Albert Sexton** \* Hartford, Conn.; Vanderbilt University School of Medicine, Nashville, Tenn., 1906; past president of the American Hospital Association, the Connecticut Hospital Association and the New England Hospital Association; assistant superintendent of the Johns Hopkins Hospital, Baltimore, 1914-1917; superintendent of the Hartford Hospital from 1917 to 1936, when he became director emeritus; aged 60; died, Dec. 3, 1936, of carcinomatosis.

**William Denison Morgan**, Hartford, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1876; member of the Connecticut State Medical Society; medical director of the Phoenix Mutual Life Insurance Company; for many years honorary chairman of the executive committee of the Hartford Hospital; aged 86; died, Dec. 17, 1936, of carcinoma of the bladder, bilateral pyelonephritis and prostatic hypertrophy.

**Thomas Warren Luce** \* Portsmouth, N. H.; Medical School of Maine, Portland, 1895; past president of the New Hampshire Medical Society; fellow of the American College of Surgeons; member of the New England Surgical Society; past president of the Rockingham County Medical Society; chief surgeon to the Portsmouth Hospital and consulting surgeon to the New Hampshire Memorial Hospital, Concord; aged 66; died, Dec. 11, 1936, of endocarditis.

**Andrew Jackson Goodwin**, Wheeling, W. Va.; University of Pennsylvania School of Medicine, Philadelphia, 1915; member of the West Virginia State Medical Association; assistant

medical adviser at Cornell University, Ithaca, N. Y., 1916-1917; served during the World War; formerly on the staff of the Mayo Foundation as fellow in surgery; on the staff of the Ohio Valley General Hospital; aged 46; died, Dec. 4, 1936, of pneumonia.

**John Chase Sexton**, Rushville, Ind.; Medical College of Ohio, Cincinnati, 1882; member and past president of the Indiana State Medical Association; past president of the Rush County Medical Society; at one time professor of gastrointestinal surgery, Indiana University School of Medicine, Indianapolis; owned and operated the hospital now known as the Rushville City Hospital; aged 77; died, Dec. 28, 1936.

**Henry Van Velsor Holcomb** \* Hempstead, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1903; fellow of the American College of Surgeons; member of the surgical staff of Nassau Hospital, Mineola, Mercy Hospital, Hempstead, South Nassau Communities Hospital, Rockville Center; aged 59; died, Dec. 23, 1936, of arteriosclerotic heart disease.

**Howard Townsend Swain** \* Boston; Harvard University Medical School, Boston, 1897; fellow of the American College of Surgeons; member of the New England Pediatric Society; at one time assistant in obstetrics at his alma mater; on the staffs of the Massachusetts General Hospital and the Boston Lying-in Hospital; aged 68; died, Dec. 6, 1936.

**Arthur Charles Echternacht**, St. Louis; State University of Iowa College of Medicine, Iowa City, 1905; member of the Illinois State Medical Society and the Radiological Society of North America; director of laboratories at the Missouri Baptist and Christian hospitals; aged 57; died suddenly, Dec. 16, 1936, of coronary thrombosis.

**Henry Lord Cochran**, New York; Long Island College Hospital, Brooklyn, 1879; formerly instructor in operative surgery at his alma mater; for many years examiner for the Commercial Travelers Mutual Accident Association of America; retired colonel of the national guard; aged 81; died, Dec. 28, 1936, of paralysis agitans.

**James Claude Kessler**, Iowa City, Iowa; State University of Iowa College of Medicine, Iowa City, 1906; member of the Iowa State Medical Society; at one time assistant professor of dermatology at his alma mater; formerly on the staff of the University hospitals; aged 56; died, January 1, of cerebral hemorrhage.

**Coleman Lovejoy Hoffman**, Oak Park, Ill.; State University of Iowa College of Medicine, Iowa City, 1903; member of the Illinois State Medical Society; veteran of the Spanish-American War; aged 58; died, Dec. 17, 1936, in the West Suburban Hospital of acute nephritis, uremia and Kimmel's disease.

**Edward Hofma**, Grand Haven, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; formerly state senator and member of the board of education; bank president; medical officer to the Wellman expedition to the north pole; aged 77; died, Dec. 15, 1936, of arteriosclerosis.

**Elmer Llewellyn Meyers** \* Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1901; fellow of the American College of Surgeons; for many years member of the city board of education; aged 72; on the staff of the Wilkes-Barre General Hospital, where he died, Dec. 17, 1936, of pulmonary embolism.

**Wayland Briggs Cunningham** \* Port Arthur, Texas; Eclectic Medical College, Cincinnati, 1928; past president of the Lincoln County (Ky.) Medical Society; member of the Kentucky State Medical Association; aged 38; died, Dec. 6, 1936, in an automobile accident at Oakdale, La.

**Eugene Howard Goodfellow**, Brooklyn; Albany (N. Y.) Medical College, 1894; served during the World War; for many years connected with the Veterans Administration; aged 66; died, Dec. 27, 1936, in the New York Polyclinic Medical School and Hospital, New York, of pneumonia.

**David Daniel Goldstein** \* New York; University of the City of New York Medical Department, 1890; fellow of the American College of Surgeons; aged 67; on the staffs of the Sydenham Hospital and Mount Sinai Hospital, where he died, Dec. 6, 1936, of streptococcal sore throat.

**William Lyman Guild**, Wayne, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1884; Chicago Homeopathic Medical College, 1892; member of the Illinois State Medical Society; surgeon to the Chicago, Aurora and Elgin Railroad; aged 77; died, Dec. 18, 1936.

**Roland Roderic Keiser** \* Mahanoy City, Pa.; Jefferson Medical College of Philadelphia, 1923; member of the city

### LONDON

(From Our Regular Correspondent)

Jan. 2, 1937.

#### Anatomic Variations of Alimentary Tract

At the annual Congress of Radiology, held in London, an important discussion took place on anatomic variations of the alimentary tract. Sir Thomas P. Dunhill dealt with the esophagus and thoracic stomach. He reported a case of short esophagus with parietal thoracic stomach sent to him with the diagnosis of carcinoma of the esophagus and roentgenograms that were supposed to show this. He made a barium sulfate examination which showed clearly a short esophagus and thoracic stomach. He subsequently saw twenty-five similar cases. In such cases an increase took place in the amount of the stomach which gradually found its way into the thorax, and then retention of contents in the esophagus produced ulceration above the narrowed stricture, with increasing dilatation. In certain cases an esophagus of normal length herniated back into the thorax. Not many cases had been seen in England until recently, though they had been reported in the United States.

#### THE STOMACH AND DUODENUM

Dr. R. B. Myles said that anatomic variations had not yet been put in their proper compartments in the English textbooks. The J-shaped stomach might be described as normal in the average person, the transverse stomach was normally seen in the person of stocky or obese build, and the long or hyposthenic stomach was perfectly normal in a long, thin patient. Alterations in the duodenum were largely dependent on the habitus of the patient. In the most normal type of orthotonic patient the duodenal cap was placed a little above the center of the duodenal loop, and the gastrojejunal junction at about the same level as the upper angle of the duodenal cap. A duodenal diverticulum showed as a smoothly rounded sac with clear-cut borders, close to the viscus, to which it was attached by a neck. In most cases duodenal diverticula were single, but occasionally there were two or three.

#### THE APPENDIX AND COLON

Dr. S. C. Shanks said that the appendix, being vestigial, was subject to many anatomic variations in length, lumen, position and mobility. The classic appearance with a barium sulfate meal was that of a blind tube 3 or 4 inches long, from 2 to 4 mm. in caliber, and showing a gentle single or double curve. There might be marked variations. Its length might be represented by a mere thread of barium, or the caliber might be 5 or 6 mm. Muscular tone and peristalsis might cause inconstant constrictions, which should be distinguished from permanent strictures. The colon might show anomalies of length, rotation, fixation or size. Congenital malformations of the rectum and anus were not susceptible to radiographic demonstration, as the alimentary canal ended blindly. But theoretically two could be demonstrated—the rectum in the male opening into the urethra by a narrow channel through the prostate, and the rectum in the female opening into the navicular fossa behind the vaginal orifice. But he could not find any record of such demonstration.

#### THE DIAGNOSIS AND TREATMENT OF CANCER OF THE LUNG

Dr. A. C. Christie said that cancer of the lung was increasing and at necropsy was found in from 5 to 10 per cent of cases of cancer. In every case it arose in a bronchus, from the indifferent epithelium in the basal layer of the mucosa. A high rate of metastasis was typical, apparently resulting from the circulation in the lung, which was intimately con-

nected with all parts of the body. The first and most frequent symptom was persistent coughing, the next pain in the chest, the third dyspnea and the fourth hemoptysis. The most important means of diagnosis was radiologic. Until recently the prognosis was considered hopeless, but now a few cured cases had aroused hopeful expectancy. A few daring surgeons in several countries had removed the cancer. The results of radiotherapy were encouraging, but it had no place as a pre-operative measure. It could usefully be directed against the tumor through the open wound. Dr. Christie referred to a woman whom he saw in 1928 with a cancer in the right main bronchus. The chest was opened and radiation directed against the tumor. She was still alive and well. He suggested that the intrathoracic application of x-rays to the stump of the tumor might be made ideally by low voltage, soft x-rays, without damage to deeper structures.

#### The Control of the Sale of Poisons

The regulations governing the sale of poisons have been greatly tightened in recent years. The passing of the pharmacy act of 1933 and the coming into force of the poisons rules of 1935 have made a great difference. Before these became effective any one could obtain deadly poisons, and at inquests coroners deplored the ease with which fatal drugs could be bought from pharmacists. The position indeed became so dangerous that the government suggested to the Pharmaceutical Society that means should be taken to prevent the indiscriminate supply of dangerous drugs, and new administrative machinery became necessary in order that the new regulations might be brought into force. Every pharmacist's shop had to be registered. The Pharmaceutical Society appointed inspectors, and membership in the society, formerly optional, became compulsory, resulting in an increase of membership from 16,000 to nearly 23,000. Such dangerous drugs as alkaloids can now be obtained only from registered pharmacists, the purchaser must be known to the seller, and the sale must be entered in a poisons register. Barbitol and other barbiturates, which have figured in so many inquests, may no longer be supplied to the public except on a medical prescription. Poisonous substances of commercial use for the destruction of vermin and other purposes, such as arsenical compounds, barium salts, strong sulfuric acid and sodium hydroxide, can still be obtained from dealers, but these have to be registered by the local authorities. No figures have yet been published showing the benefit derived from the new regulations, but they render it much more difficult to obtain poisons for self drugging or for criminal purposes and should therefore diminish the numbers of cases of accidental, suicidal and criminal poisoning.

#### Sir John Bland-Sutton

Sir John Bland-Sutton, surgeon, anatomist, comparative anatomist, pathologist, comparative pathologist, naturalist and traveler, has died in his eighty-second year. This list shows why the *Times* remarks that the profession has lost "a type of surgeon so rare as to be produced only once or twice in a century," and it might have added "only in Britain." Other countries have of course produced their great men in all these sciences but it is their cultivation by a foremost surgeon that is peculiar. The Swiss physiologist Haller of the eighteenth century might be supposed to be an example. He was equally eminent as an anatomist and botanist but, though he lectured on surgery, he never performed an operation. The first and greatest example of the type of Bland-Sutton was "the father of scientific surgery," John Hunter, who took life itself for his study. It does not seem likely that any more men of this type will be produced, for we live in an age of increasing specialism, in which workers "know more and more about less and less."

The son of a field naturalist, he followed his father's bent and wrote in his *Introduction to Pathology* "born and edu-

### A SIMPLE METHOD FOR LOOSENING STUCK SYRINGES

*To the Editor:*—Often stuck syringes are encountered and there are no special devices available to loosen them. Unless hopelessly stuck, they may easily be loosened with materials found in any physician's office. The smallest syringe at hand, a tuberculin or a 2 cc. syringe, is filled half full of water and a one-half inch hypodermic needle is attached. The needle is passed through a thickness of rubber, such as a rubber band, and then inserted firmly into the tip of the stuck syringe. Pressure is then made on the plunger of the syringe containing water, which in turn is transmitted to the stuck plunger, forcing it loose. The smaller the area of the end of the free plunger to that of the stuck plunger, the greater the hydraulic advantage obtained. Some care should be used in attempting to free badly stuck syringes by this method.

J. B. HOPKINS, M.D., Richmond, Va.  
601 State Office Building.

### REDUCING FLUIDS FOR REMOVING SILVER PIGMENTATION

*To the Editor:*—Dr. Cornbleet, in his communication published in THE JOURNAL Dec. 12, 1936, page 1989, criticizes the use of the term "reducing fluid" with reference to the mixture of potassium ferricyanide and sodium thiosulfate used in removing silver pigmentation from the skin. I have no doubt that the writer of the answer to the query which Dr. Cornbleet criticizes used the term "reducing fluid" in the same way that it was used by Dr. Lawless and myself in our articles on the subject, that is, a photographic reducing fluid, a fluid which reduces overexposed negatives. In this sense I believe Dr. Cornbleet will grant the propriety of the expression.

On the other hand, how does Dr. Cornbleet know that the mixture used, containing 1 per cent potassium ferricyanide and 6 per cent sodium thiosulfate, is an oxidizing agent in the chemical sense? Other eminent chemists confess their uncertainty on this point. The reactions in vitro are much more complicated than the formulas offered by Dr. Cornbleet. Furthermore, the reaction in the tissue are wholly unknown. We do not know the nature of the light colored form of silver deposited in the upper cutis, which turns dark on exposure to light. Until we know this and a great deal more about the effect of tissue fluids on chemical reactions in the skin, it seems to me presumptuous to give formulas.

A. W. STILLIANS, M.D., Chicago.

### SUBCUTANEOUS EMPHYSEMA IN ASTHMA

*To the Editor:*—In view of the rarity of cases of subcutaneous emphysema complicating asthma as reported by Sheldon and Robinson in THE JOURNAL, Dec. 5, 1936, an additional case report may be of interest:

S. R., a boy, aged 6, a home relief client, was seen Dec. 7, 1934, in an acute attack of asthma. He had been having paroxysms for the past year. The family history was negative for allergic disorders. The attack was relieved after exhibition of codeine, ephedrine and calcium, and the patient (because of financial conditions) was referred for study to an outpatient clinic. He was found sensitive to house dust, and desensitization was undertaken. The paroxysms diminished in frequency, and for seven months preceding the following occurrence he was free from symptoms.

Nov. 3, 1936, he had a severe attack of expiratory dyspnea. The following day I was called because swelling of the face

had appeared. Examination revealed the dyspnea, pulmonary emphysema, râles and rhonchi of a subsiding asthmatic attack. There was a pronounced swelling of the left parotid and submaxillary regions. There was palpable crepitus over these regions as well as the anterior and posterior triangles of the neck, the left axilla and the left pectoral region. In the following two days the emphysema spread to the right pectoral region. Of especial interest is swelling and tenderness of the lower gum margins, which appeared on the second day and subsided with the other signs.

With strict rest, suppression of coughing with codeine, and ephedrine, the dyspnea and emphysema gradually cleared up in the following six days.

This case corroborates the report of Sheldon and Robinson with respect to the factors of age, occurrence after an interval free from attacks, and good prognosis.

FREDERICK BRIDGE, M.D., Brooklyn.

### MYCOBACTERIUM LEPRAE

*To the Editor:*—In the abstracts from the *Medical Journal of Australia* published in THE JOURNAL January 2, page 78, the causative agent of lepra is referred to as "Mycobacterium leprae." Misspelled words are so frequently and often unintentionally introduced into medical nomenclature that they should be corrected on every occasion. The proper designation is "Mycobacterium leprae." The organism is one of the Mycobacteriaceae. Although Hansen in 1874 identified it as a bacillus, its classification by Lehmann-Neumann has been generally accepted since 1896.

FRANK C. COMBES, M.D., New York.

### GASTRIC ACIDITY AND GASTRIC ULCER

*To the Editor:*—In an editorial in THE JOURNAL, Dec. 19, 1936, the important relationship of gastric acidity to experimental ulcer in animals, as well as gastric and duodenal ulcer in man, seems to have been definitely shown. However, the statement "within wide limits the concentration of pepsin appears to be of no importance" justifies further discussion. Recent clinical observations of Vanzant, Osterberg, Alvarez and Rivers (*J. Clin. Investigation* 12:557 [May] 1933) confirmed by Mullins and Flood (*ibid.* 14:793 [Nov.] 1935) seem to indicate that peptic ulcer in man is frequently accompanied by an increase of pepsin as well as of acidity.

Animal experimentation likewise points to the probable important rôle of pepsin in the pathogenesis of ulcer. Howes, Flood and Mullins (*Surg., Gynec. & Obst.* 62:149 [Feb.] 1936) reported that operatively produced gastric defects in cats showed a greater delay in healing in those receiving pepsin with acid, as compared to those receiving acid alone. Recent experiments reported by Matzner, Windwer, Sobel and Polayes (*Proc. Soc. Exper. Biol. & Med.* 34:243 [March] 1936) and Matzner and Windwer (*Am. J. Digest. Dis. & Nutrition*, to be published) appear to indicate that pepsin in an acid medium is far more effective than hydrochloric acid alone in the experimental production of gastric ulcer in rats.

While the corrosive action of hydrochloric acid on living tissue appears to have been established, experimental evidence would seem to indicate that pepsin in an acid medium is the more important factor. Further study in the control of pepsin secretion in conjunction with that of gastric acidity should prove of interest.

MILTON J. MATZNER, M.D.  
CHARLES WINDWER, M.D.

Brooklyn.

Department of Gastro-Enterology,  
Jewish Hospital.

cal control is at present organized not only for the purpose of observation during the six months' period of indemnity for a single ailment but also from the time a case is reported to the caisses or primary disbursing bureaus. Without such a medical control it is impossible to ascertain whether the insured has been really unable to work, whether expensive pharmaceutical preparations not allowed by the caisses (disbursing bureaus) have been employed, whether laboratory examinations have been made and treatments administered which appear superfluous in the given case and, finally, whether the stay in a hospital has been unnecessarily prolonged. Frauds are frequent in social insurance and can be avoided only by strict medical control. The abuses cited apply equally to dental care, because experience has shown that the bills for such services often exceeds those asked for operations. If the control does not function in all medical and dental cases from the onset of the illness, it is impossible to follow the serious ones and suggest a treatment which may not only greatly aid the patient but also save a great deal of outlay on the part of the respective social insurance bureau. In the case of those who are more or less permanently incapacitated and who are entitled not only to an invalidity pension but also to medical care during the first five years, the latter also needs constant supervision. Only institutions that have made a contract with the social insurance authorities shall be allowed to care for this class of cases, in order to cut down the expense as much as possible without neglecting the needs of the insured.

Instead of a central caisse or collecting and disbursement bureau for each of the eighty-six departments (counties) in France, the country is divided into a smaller number of regional bureaus. Each of the latter now has its technical commission to arbitrate any dispute between the report of the medical inspector and the insured. If the latter is not satisfied with the amount allowed for the outlay for a given illness and the time granted for absence from work, the insured can appeal to the regional technical commission, which will make an examination of the claimant and decide whether the indemnity is an adequate compensation in the given case. The technical commission is composed of the medical inspector of the regional bureau, a chairman who is a physician, and a medical expert appointed by the local judge of the civil court.

#### Poliomyelitis in Paris During the Last Three Years

At the December 1 meeting of the Académie de médecine a report covering the observations of the health department of Paris and its suburbs on the incidence of poliomyelitis was made by Tanon and Besson. The main features of the spread of the disease are the part played by carriers and the occurrence of atypical and abortive cases. In 1933 there were fifty-six cases with seventeen deaths, in 1934 forty-three cases with twenty-two deaths, and in 1935 seventy-two cases with nineteen deaths. Although the incidence as a rule is higher toward the end of summer and beginning of autumn, there was a sudden increase in December 1934 and January 1935. As to the age of the patients, thirty-four were less than 3 years old, sixty-four between 3 and 8 years of age and nineteen from 21 to 32. In the case of school children they always belonged to different classes and there did not appear to be any contact between them. No two cases were found in the same flat or family. This shows that, at least in Paris, contagion does not play an important part. The patients are usually hospitalized as soon as possible.

#### Vaccination with Cultures of the Vaccinal Virus

At the December 1 meeting of the Académie de médecine Drs. Harry Plotz and René Martin reported their results in the clinical application of cultures of vaccine virus as a substitute for that obtained from cows. The vaccine virus was cultivated by means of the Li and Rivers method with the

slight modification of using 75 cc. Erlenmayer flasks in place of the "collar flasks" (as employed by Rivers) and 3 cc. of Tyrode's solution without serum. By this means a cerebral, dermal and testicular strain was cultivated, one strain reaching 152 passages. The virus remains active for rabbits but has a tendency to decrease in virulence in subsequent transplants. The culture virus was dried by the Flosdorf-Mudd apparatus and this vaccine has been used to vaccinate children in the same manner as was employed by Rivers, Ward and Rivers, and Herzberg. The first series vaccinated comprised fifty-seven children. They were vaccinated on one arm with the culture vaccine and on the other with the usual vaccine. Nineteen of the children were immune to both inoculations and showed no reaction on either arm. Of the thirty-eight positive with the usual vaccine, only nineteen were positive with the culture virus. As 0.1 cc. was injected intradermally, the authors thought that the amount of vaccine injected was insufficient. In a second series of forty-four children, 0.2 cc. was used. Of this series, twenty-one children showed "typical" reactions on both arms. Four were positive with the usual vaccine and negative with the culture virus, while four others were positive with the culture virus and negative with the usual vaccine. The other children were immune to both vaccines. The positive results obtained with the culture virus are characterized by a typical but slightly local and general reaction as well as a slight scar.

#### The Economic Condition of University Docents

The economic condition of the younger generation of German University instructors has never been particularly favorable unless the young assistant or docent received money from home or had some other private income. In the hope of some day succeeding to a professorial chair, these men must meanwhile carry on their academic activities while forced to live on a restricted budget. This bad economic situation cannot fail to exert its influence on both mind and character, and many a university professor may carry throughout his life the scars of these early privations. For some time a better regulation of the living conditions of the private docents has been under discussion. Remedial measures have become all the more necessary as the opportunities for making a living in the academic field have been each year more circumscribed so that in the end only the few attain the goal; namely, appointment to a professorship. Scholarly enterprise must perforce suffer from this unfortunate situation and many academicians are forced to enter side lines of professional activity. It frequently happens that the most able of these young men transfer their services to the world of industry. Speedy remedial measures are necessary if Germany is to maintain secure her world-renowned tradition of scholarship. This problem is dealt with exhaustively in the "Amtsblatt des Reichs- und Preussischen Ministeriums für Wissenschaft, Erziehung und Volksbildung." It is not encouraging for an assistant 25 or 26 years of age to earn a monthly stipend of from 80 to 200 marks, and he himself later as a docent must have at least a teaching commission if he is to earn a better income. After years of research the docent receives the title of assistant professor, but even this signifies no economic betterment. Only an appointment to the rank of full professor in ordinary or extraordinary entails relief from economic pressure. But such an appointment, it should be repeated, is reserved for the few.

As a result of the situation, the rising generation of academicians have resorted to cooperative aid. The national minister of public instruction has created a "Reichs-Dozentenwerk" or National Docents' Self Help Organization, the duty of which is to render financial assistance to needy university graduates.

the skin and never enters the follicle. The growth penetrates the hair to some degree, causing it to become brittle and often break. The growth of the fungus alone causes a yellow coloration. A bacillus or coccus-like growth added to it causes red or brownish.

For pseudochromidrosis it is necessary only to give some antiseptic, such as mercury bichloride 1:1,000 in alcohol. Dabbed on once or twice daily, it soon destroys the growth.

#### ETIOLOGY OF MISCARRIAGES

*To the Editor:*—A woman, aged 30, height 5 feet 5 inches (165 cm.), weight 110 pounds (50 Kg.), of exceedingly nervous type, has been married ten years and has no children. Numerous examinations have been repeatedly negative. Blood Wassermann tests and urinalyses have always been negative. The basal metabolic rate a year ago was minus 22. Thyroid therapy was instituted and six months later the basal metabolic rate was minus 10. The patient is still on thyroid, 2 grains (0.13 Gm.) daily. Three years ago the patient had a miscarriage at two months. Two years ago another miscarriage occurred at three months. Six months ago there was another miscarriage at three months. Both husband and wife desire children. Prostatic massage of the husband revealed a chronic prostatitis of unknown duration. It is unquestionably nongonorrheal. The husband is 30 years of age. Examination of his semen (condom specimen) shows numerous actively motile spermatozoa. Is it possible for the prostatitis to cause the miscarriages? Can the hypothyroidism alone be the disturbing element? What are the chances of carrying a pregnancy to term? Please omit name and address.

M.D., Kentucky.

**ANSWER.**—The fact that the patient does become pregnant is definitely in her favor. Without a question, the hypothyroidism in the patient and the prostatitis in the husband can be factors in the production of abortion, the former because of imbalance in the endocrine chain and the latter because of the possibility of having the spermatozoa affected and thus resulting in an improperly formed fetus. The hypothyroidism should have been adequately controlled by the use of thyroid.

The possibility of carrying the patient to term is problematic, but efforts in that direction can be made which should increase the chance for a happy termination.

Every effort should be made to clear up the prostatitis in the husband. In the event that the patient should become pregnant she must be put to bed for the first five months, with all exercise and sexual intercourse eliminated. Recent work tends to show that progesterone (corpus luteum hormone) is a valuable aid in the treatment of such patients, this hormone acting to cut down on uterine irritability and activity. Progesterone should be used in doses of 1 international unit every other day, hypodermically, for the first five months and at any time thereafter that signs of impending abortion or of premature labor present themselves.

#### CHRONIC PAROTITIS

*To the Editor:*—A 6 year old girl has had intermittent attacks of pain and swelling in the parotid glands accompanied by a temperature rise up to 102 F. every two or three months for the past two years. The condition lasts from three to twelve days and occurs most often on the right side but has been bilateral and on the left side only twice. Pus can be expressed from the duct, but smears are negative for bacteria. X-ray films and probing of the ducts have not revealed any calculi. The past history is entirely negative except for a tonsillectomy, which was done two months before the first attack. Please give me some information as to diagnosis and treatment of this condition.

JOHN H. CLARK, M.D., Vernal, Utah.

**ANSWER.**—The patient is probably afflicted with the symptom complex known as "chronic Sialodochoparotitis with recurrent subacute exacerbations." The swelling of the parotid gland or glands in this condition has a tendency to recur and may be slightly painful. It may last from several hours to several days or weeks, the gland remaining moderately enlarged between exacerbations. In some instances the swelling appears in the morning and disappears after breakfast. The salivary secretion is usually not affected, although some patients may complain of excessive discharge of pus and saliva from the affected gland. There is as a rule no febrile reaction, and the general health is apparently unaffected. The patient may learn to obtain relief by pressure over the gland with the resultant discharge of pus or saliva, or, as in the condition of "fibrinous sialodochitis," by removal of a plug of fibrin from the duct.

There is usually no apparent predisposing cause, although cases following tonsillectomy, tonsillitis and tooth extraction have been reported.

On examination during the recurrences, one finds an enlarged, firm, occasionally nodular gland, which may be slightly tender to pressure. The overlying skin generally shows no changes, but at times it has been observed to be red or even fluctuant.

The duct is not palpable unless it is stenosed or there has been a long standing fibrous sialodochitis. The duct opening and papilla may or may not be red. Pressure on the gland may cause the appearance of pus, a cylindric mass of fibrin and pus, cloudy saliva or unaltered saliva.

Therapy may be either nonsurgical or surgical in nature. Nonsurgical procedures would include dilatation of the duct and massage of the gland, general care, eradication of foci of infection, such as infected teeth, iodides, injection of mild antiseptics or irritants (as iodized poppy-seed oil or mercuriochrome) into the duct, x-rays, epinephrine, and foreign protein therapy.

Surgical procedures might indicate slitting of the duct, slitting or removal of the stenotic portion of the duct, extirpation of the auriculotemporal nerve with resultant atrophy of the gland, or removal of the gland.

A report of such a case, with complete literature, may be found in the article by Sol Londe and Mort D. Pelz (*J. Pediat.* 2:594 [May] 1933).

#### DIAGNOSIS OF CHONDROMA

*To the Editor:*—A young married woman, aged 23, and the mother of one child, aged 11 months, has an enlargement at the sternal end of the third left rib. This was noticed about four years ago as a small lump and was slightly tender to pressure. She consulted a competent Chicago surgeon, who had an x-ray examination made by a competent roentgenologist. No pathologic condition was visualized, no diagnosis was made, and nothing was done. Since that time the lump has slowly enlarged until now it is about the size of half-dollar piece (30 mm.) and is plainly visible on inspection. There is tenderness, to pressure, which varies from time to time, and also there is slight pain in this region occasionally. The enlargement is smooth; the overlying skin is attached or discolored. No cervical or axillary lymph glands are palpable. The breast tissue appears to be normal. A short time ago another surgeon was consulted, who roentgenographed the chest in this region. As before, nothing was visible. No diagnosis was made. The past history of the patient is as follows: Tonsillectomy was done when she was a child, appendectomy in 1931, gallbladder drainage in 1932, and cholecystectomy in 1933 for chronic cholecystitis. The Wassermann reaction is negative. Since the surgery mentioned her health has been good, except that in the past year she has become easily fatigued from ordinary housework. Her weight is 110 pounds (50 Kg.), but this varies between 110 and 115 pounds (52 Kg.). Her pregnancy was uneventful and delivery was normal. Please omit name.

M.D., Illinois.

**ANSWER.**—In 213 collected cases of tumors of the ribs and sternum (Parham, Lurd and Hedblom), cited by Lewis, Dean: (Heuer, G. J., and Andrus, W. De W.: *Tumors and Cysts of the Thorax*, in *Practice of Surgery*, Hagerstown, Md., W. F. Prior Company, Inc., 1930, vol. 5, chapter 5), sarcoma occurred in 131, chondroma in forty, carcinoma in twenty-four, fibroma in five, exostosis in three and gumma in one. The slow enlargement of the tumor in this case, its location, its smooth contour, and the relative absence of symptoms, lead to the conclusion that it is probably a benign chondroma. In the Mayo series, however, four cases subjected to radical operation and seven subjected to biopsy proved to be inflammatory lesions.

Accurate diagnosis can probably be made only after biopsy. Treatment for a primary tumor, whether benign or malignant, would be by excision of the sternal portion of this third rib.

#### EFFECTS OF ETHANE AND METHANE ON NASAL MUCOUS MEMBRANES

*To the Editor:*—Could you give me information regarding the effect of ethane and methane gases on the nasal mucous membranes? I have in mind a patient with a severe atrophic rhinitis who has been working in natural gas fumes for several years. I feel that the patient's work is probably deleterious to his nose. Can you give me any confirmation in this regard?

J. H. BRISTOW, M.D., Bay City, Mich.

**ANSWER.**—Ethane (C<sub>2</sub>H<sub>6</sub>) and methane (CH<sub>4</sub>) are common constituents of illuminating gas. Methane is the principal component of fire damp in coal mines. It is stated not to have any physiologic effect on man. Ethane is ordinarily not found in fire damp but has been said to be present in certain German mines. As fire damp is not known to have a direct action on man, ethane is probably harmless. One may breathe an atmosphere of methane and oxygen for a long time without apparent deleterious effects provided the amount of oxygen remains above 21 per cent. References are:

Kober, C. M., and Hayhurst, E. R.: *Industrial Health*, Philadelphia, P. Blakiston's Sons & Co., 1924.  
Oliver, Thomas: *Dangerous Trades*, London, John Murray, 1902.

Neither the rhinologic literature nor that pertaining to industrial hazards makes mention of irritating or deleterious effects of these gases on the mucous membranes of the nose.

the science of balneology in the Balkan states. Among the Rumanian physicians was Professor Gheorghiu, rector of Bucharest university. The Rumanian members read nine papers, in which they endeavored to emphasize Rumania's natural balneologic resources. Among the Jugoslavian physicians was Professor Benzis and among the Greek physicians Professor Matcovici, professor of materia medica at the University of Athens. They voted to hold the next congress at Athens in 1938.

#### Choice of Occupation by Female Medical Students in Case of War

The Bucharest war ministry sent circular blanks to all female medical students and women physicians in the country asking what occupation they would choose in case of war. The overwhelming majority of students answered that they would prefer to act as hospital nurses, while the women physicians answered that they should like to work in military hospitals as well as on the field and in the hinterland.

#### Students' Strike at Cluj University

Students of the university of Cluj Faculty of Medicine went on strike three days ago. Today a deputation of the students handed a memorandum to the dean of the faculty demanding the exclusion from the faculty of all minority students. They stated that the medical students will not appear at the lectures as long as the faculty does not withdraw the punishment of Vucu, secretary of the association of medical students, and of Dumitrescu, president of this association. The university magistrates had found these two students guilty of causing disorder in connection with the examinations for admittance to the faculty. The aim of the disturbance was to keep Jews from passing the examination. For this offense the board of the faculty sentenced both leaders to exclusion from two terms. Thereupon the rest of the medical students went on strike, and it is not at all impossible that the strike will extend also to the other faculties of Cluj University.

### ITALY

(From Our Regular Correspondent)

Nov. 30, 1936.

#### Sanitary Regulations for Airplanes

Colonel Dr. Porru of the Istituto Medico-Legale Aeronautico of Florence, in a recent lecture considered the health measures that should be adopted in air ports and aboard airplanes for the prevention of infections, such as examining the travelers on their arrival and departure. This measure is already provided for in Italy: Physicians are on duty at the airports at all times for the purpose of making the examinations. Persons found suffering from infections are isolated in the airport hospital and later are sent by special ambulance to municipal hospitals. The speaker advised the establishment in aviation of a clean bill similar to that used in navigation. The prevention of plague, cholera, smallpox, exanthematic typhus and yellow fever is given wide attention, especially because of the fact that traffic and aviation between Europe and the countries where the diseases are frequent has increased. Prevention of yellow fever is of the utmost importance because of the frequency of the disease in Africa, the abundance of transmissive insects in that country and the increase in traffic and aviation between Europe and Africa. Yellow fever is also frequent in natives of Anglo-Egyptian Sudan, a zone of heavy traffic also. The speaker referred to work by Dr. Trolli, head physician in the Belgian Congo, who found that insects which transmit yellow fever may enter airplanes during their stay in airports and be carried in the airplane to great distances at the speed of 2,000 kilometers a day. The speaker advised such preventive measures as examination of the plane and, in certain cases,

its disinfection and also medical examination of the passengers for six consecutive days, especially if quarantine is not established at the given zone. To prevent infections, the Air International Committee of Sanitation was established in 1933. Air posts of all nations belonging to the committee should have airports in which quarantine can be applied and disinfection performed. There are now ten sanitary air posts and many other "authorized" air posts in Italy. "Authorized" air posts have not all resources that sanitary air posts have, but all work on hygiene and prevention of infections is carried on by physicians who take turns, so that their services are available at any time.

#### Personals

Prof. Rocco Iemma, vice president of the Società Internazionale di Pediatria, director of the Clinica Pediatrica of Naples University and a well known Italian pediatrician, resigned his positions because of having reached the legal age limit (70 years). Six of his pupils are regular professors, forty are free professors and twenty are directors of hospitals or foundling homes. The scientific contribution of Professor Iemma's school exceeds 900 important articles, including those on specific treatment of leishmaniasis in children, vaccine therapy in typhoid and paratyphoid, tuberculosis in children and preventive vaccination of tuberculous diseases. When Professor Iemma served thirty years as professor, homage was paid him by the collaboration of fifty-two official scientific centers. Original articles were published also in his honor by 120 scientists both in Italian and in foreign countries.

General Dr. Franchi, the head of military sanitation, has also reached the age limit, and General Lieutenant Dr. Loreto Mazzetti, professor of hygiene at the University of Rome, has been appointed to the position. Dr. Mazzetti was the head of the laboratory of chemical and clinical bacteriology of the Naples Hospital. During the war he organized the isolation hospital in Udine. He was the director of the Ospedale Militare e di Sanita della Tripolitania and later of the School of Sanitation of Florence.

### Marriages

---

THOMAS STRICKER EDDLEMAN to Miss Frances Mae Strickland, both of Charleston, S. C., in Tarboro, N. C., Nov. 12, 1936.

STANLEY EARL COPELAND, Worcester, Mass., to Miss Harriet Estelle Wentworth of Oxford, in New York, Nov. 28, 1936.

DONALD ELLISON MACGREGOR, Indianapolis, to Miss Allison Priest Arnold of Louisville, Ky., Dec. 24, 1936.

GUS WARLICK NEECE, Fort Moultrie, S. C., to Miss Mary Elizabeth Davis of Mayo, Fla., Dec. 12, 1936.

OSCAR THOMPSON WOOD JR., Philadelphia, to Miss Frances Joan Travers in Millville, N. J., Dec. 5, 1936.

HENRY GEORGE ATHA, Providence, R. I., to Miss Grace MacTavish, in Groton, Conn., Nov. 16, 1936.

WILBUR OGDEN ARNOLD to Miss Olive Edith Schell, both of West Palm Beach, Fla., Dec. 5, 1936.

JAMES HARRY BUNN JR., Baltimore, to Miss Frances Middleton of Aberdeen, Md., Nov. 26, 1936.

ELDRIDGE T. NORMAN, Linden, Ala., to Mrs. Janie T. Harrison of Montgomery, Ala., Dec. 1, 1936.

CLIFFORD F. BRODERICK, Stevens Point, Wis., to Miss Ruth Potton of Milwaukee, recently.

JULIANNA RANDOLPH TATUM, Radnor, Pa., to Mr. Harvey Chace Perry, Dec. 12, 1936.

JOHN O. BARFIELD to Miss Edith Herlong, both of Miami, Fla., Dec. 1, 1936.

JOHN L. BAUBE, New York, to Miss M. F. Robinson of Clio, Ala., Dec. 26, 1936.

GEORGE K. ARNOLD, Dallas, Texas, to Miss Mae Sue Day, Dec. 1, 1936.

## GASTRIC PSYCHONEUROSIS

*To the Editor:*—I have a case that has puzzled me and many others. A man, aged 51, was always healthy until two years ago, when he noticed inability to breathe deeply. He does not have dyspnea when working, but after meals when quiet he feels a fullness. He used to get relief on raising gas, but now he gets no relief, do what he may. He has been to many clinics. Stomach examinations reveal no organic disease of any kind, every organ appearing normal. Atropine gave some relief. Bromide and alkalis gave temporary relief. There is no pain. The patient's weight is 175 pounds (79 Kg.), height 6 feet (183 cm.). He has a strong physique. He is very nervous about himself. He says he must get relief or he will die. The attacks are worse when he is nervous and worse after a hearty meal. There seems to be neurosis of the pneumogastric nerve. He gets palpitation of the heart often. He is a dredging engineer, doing clerical work, drawing and blue prints. Motor action of the stomach is good at all times—overactive. The stools and urine are normal. There is patency of the pylorus. No obstruction exists. Could it be neuritis of the pneumogastric nerve? Do not use my name.

M.D., California.

**ANSWER.**—Physicians who have much to do with the treatment of psychoneuroses are well acquainted with the syndrome described. The patient first complains of shortness of breath, but a little questioning soon reveals the fact that the trouble does not come with exertion, and the cardiac reserve is excellent. The real trouble is that the patient has the feeling that he can't take a deep breath.

The trouble commonly comes at times when the patient is quiet and perhaps in bed. In many cases, as in this one, the patient also has a cardiac neurosis with palpitation. Or in many cases he goes to the gastro-enterologist to get relief because of air swallowing or some other form of gastro-intestinal neurosis.

So far as is known there is no organic basis for this trouble and it usually disappears as soon as the patient can be convinced that it is purely an annoyance without any danger whatever. The patient can be assured that no one ever died of this or came to any bad end.

At times it might help to give some bromides, but the main reliance should be placed on reassurance and on getting the patient to see the true nature of his trouble. Rather typical of these cases is the man's statement that he must get relief or he will die. Once such people are convinced that the symptom is of no importance, they lose interest in it. The more the patient goes to physicians, the worse he is likely to be.

DIFFERENTIAL DIAGNOSIS OF DISEASE  
OF NERVOUS SYSTEM

*To the Editor:*—A woman, aged 34, suffers from profound tiredness, a feeling of sand under the skin of the finger tips, tingling underneath the tongue, and modified similar sensations in the soles of the feet and in the toes. She is well nourished and examination gives generally negative results except for the following: The blood pressure is 100 systolic, 60 diastolic. The knee jerk and the biceps and triceps reflexes are absent. There is a suggestive Romberg sign. The Wassermann reaction is negative, as are also sensations of pain and touch. The blood picture is as follows: hemoglobin, 68 per cent; white blood cells, 5,100; red blood cells, 4,740,000; polymorphonuclears, 29 per cent; lymphocytes, 66 per cent; mononuclears, 5 per cent; color index, 0.72. The red cells are pale and show variation in size and shape. What could be the possibilities in such a picture? Please omit name.

M.D., Maryland.

**ANSWER.**—These data are insufficient for a diagnosis. The low blood pressure and high lymphocyte count may mean some endocrine disorder. If all tendon reflexes are absent, one might think of tabes or multiple neuritis. If the pupils do not react to light, the spinal fluid should be examined. In spite of the normal blood count, a diagnosis of combined cord degeneration would be suggested in case there is no free hydrochloric acid in the stomach contents. A gastric analysis after a test meal is strongly recommended.

## ADAMS-STOKES SYNDROME

*To the Editor:*—In Queries and Minor Notes in THE JOURNAL, Aug. 15, 1936, "Tobacco and Heart Disease," should not Stokes-Adams syndrome be considered with a pulse of 56? Please omit name.

M.D., Illinois.

**ANSWER.**—The possibility of an attack of the Adams-Stokes syndrome in this case is remote. However, it should be thought of in every instance of syncope not readily explained. The points against its occurrence here are, first, the fact that the pulse was reported to have been very slow at any time (a rate of 56 is frequently found normally); second, the fact that the electrocardiogram showed apparently no evidence of delayed auriculoventricular conduction when it was taken shortly after this attack; and, third, the great infrequency of the Adams-

Stokes syndrome as a cause of syncope. It is a possible but rare coincidence to have paroxysmal heart block responsible for syncope in a person who shows no electrocardiographic evidence of heart block between attacks.

## PHOBIA AND NEURITIS

*To the Editor:*—I have under my care at present a white man, aged 49, married, a merchant, who has been complaining of a tingling and burning sensation over the hypothenar eminence of both hands since January 1936. He states that the symptoms first started with a burning sensation under the fingernails of both hands associated with brittle, longitudinally grooved nails, which broke off easily. The sensation of the tingling often involves the ulnar half of the little fingers and the tip of all the other fingers. At times the fingers feel drawn, as if they had been soaked in hot water for some time. Since the onset of the symptoms, the patient has complained also of excessive salivation, which leaves a salty taste. The past history is essentially negative except for a tonsillectomy and adenoidectomy, and also incision and drainage of a perianal abscess in January 1936. Laboratory work including urine, blood count and the Wassermann test all give clinically negative results. The blood pressure is 120 systolic, 85 diastolic. Physical examination, with the exception of a well defined reddening over both hypothenar eminences, shows no evidence of any defect. One thing that I failed to mention in the past history was the fact that the patient developed a phobia of having a barber apply a razor to his face or neck. This fear began about three years ago without there being any given cause or reason. Since this phobia set in the patient states that he has never really felt right. I would appreciate any information, advice or procedures that you can offer me in reaching a diagnosis and treatment for relief of the symptoms. Kindly omit name and address.

M.D., Pennsylvania.

**ANSWER.**—The phobia of having a barber shave him is a matter for detailed psychiatric study, during which the factors individual to the patient and having a possible relation to his fears must be worked out. The tingling and redness of the ulnar surfaces of the hands suggest an occupational type of neuritis. It may be that the patient performs some routine maneuver which implicates the ulnar nerve at the wrist or even at the elbow.

## EXCITED STATES IN INSANITY

*To the Editor:*—My colleagues and I, working in a medical hospital under state supervision, have frequently been troubled by the problem as to what medication to use in the control of patients who are exceedingly active either because of a manic condition or because of the extreme agitation of involutional psychosis. We were astounded to learn that the effective intravenous dose of one recommended medication was \$1.40. Of course, economy is a primary consideration and we would be very glad if you would give us your idea of an effective agent which would be inexpensive and would lend itself to oral, intramuscular or intravenous use. A medication of prolonged action, low toxicity and lending itself to easy administration would be of tremendous value in this type of work. There is such a welter of medicaments put out by various firms that it is difficult to choose wisely and your assistance would be greatly appreciated.

WILLIAM K. McCANDLISS, M.D., Trenton, N. J.

**ANSWER.**—An economical and efficient treatment of excited states in the insane is to give 15 cc. or more of paraldehyde in olive oil or liquid petrolatum oil by rectum. Pure paraldehyde may be given in 4 cc. doses intravenously, but the injection must be given very cautiously in the course of four or five minutes, and only by a physician. A combination of scopolamine hydrobromide and morphine hypodermically is usually effective. For extreme outbreaks of fury and violence a hypodermic injection of apomorphine is most effective, and the disagreeable after-effect is likely to make a prolonged impression on the patient.

## ETIOLOGY AND PROPHYLAXIS OF ROUND SHOULDERS

*To the Editor:*—A 7 year old boy, in excellent physical condition, more robust and vigorous than the average for his age, and with a negative past history, is gradually developing a tendency to sit round shouldered. The father is quite round shouldered (but can pull himself erect) both sitting and walking; the father's father and grandfather had the same habitual postural defect. The father is worried and I would greatly like to help him. Your suggestions will be greatly appreciated. If published, please omit name.

M.D., Illinois.

**ANSWER.**—A 7 year old boy in excellent physical condition whose father and grandfather had round shoulders ought to have a complete physical examination. There should be roentgenograms made of the whole spine to discover whether or not there are any disturbances in the formation or development of the vertebral bodies.

Round shoulders may be a result of eye and ear disturbances; also disturbances in the upper respiratory tract such as enlarged adenoids or tonsils, bad postural habits, and muscular imbalance. Round shoulders follow fatigue subsequent to long continued illnesses. They are also seen in cases of chronic foot strain.

board of health; on the staff of the Locust Mountain State Hospital, Shenandoah; aged 37; died, Dec. 3, 1936, in the Jefferson Hospital, Philadelphia.

**Genous Sanders Hodges**, Marianna, Fla., Atlanta (Ga.) School of Medicine, 1912; member of the Florida Medical Association; served during the World War; county physician; formerly on the staff of the Baltzell Hospital; aged 54; died, Dec. 9, 1936, of pneumonia.

**Harry Hubbard**, Tiltonsville, Ohio; College of Physicians and Surgeons, Baltimore, 1899; formerly member of the state legislature of West Virginia; aged 63; on the staff of the Martins Ferry (Ohio) Hospital, where he died, Dec. 11, 1936, of coronary occlusion.

**Otto Vernon Greene** • Bethel, Vt.; Baltimore Medical College, 1903; for many years health officer and town physician of Bethel; member of the staff of the Gifford Memorial Hospital, Randolph; aged 56; died, Dec. 6, 1936, of cerebral hemorrhage.

**Joseph C. Higdon**, Belzoni, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1896; member of the Mississippi State Medical Association; aged 69; died, Dec. 12, 1936, in the Baptist Hospital, Memphis, Tenn.

**Edward Homer Kinsman**, Toronto, Ont., Canada; University of Western Ontario Medical School, London, 1931; member of the American Psychiatric Association; on the staff of the Ontario Hospital; aged 37; died, Nov. 29, 1936.

**Samuel D. Donovan**, Dewey, Ill.; St. Louis College of Physicians and Surgeons, 1905; member of the Illinois State Medical Society; aged 53; on the staff of the Mercy Hospital, Urbana, where he died, Dec. 9, 1936, of carcinoma.

**Frederick Dracass**, St. Petersburg, Fla.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1886; aged 89; died, Dec. 3, 1936, of arteriosclerosis.

**George Steven**, Byron, Minn.; Rush Medical College, Chicago, 1903; member of the Minnesota State Medical Association; aged 57; died, Nov. 15, 1936.

**George H. Woods** • Pine Grove Mills, Pa.; Jefferson Medical College of Philadelphia, 1875; aged 84; died, Nov. 23, 1936, of cardiac decompensation.

**William Washington Mathis**, Taylor, Miss.; Memphis (Tenn.) Hospital Medical College, 1887; aged 84; died, Nov. 30, 1936, of chronic nephritis.

**Alvin Jackson Rogers**, Los Angeles; College of Physicians and Surgeons, Keokuk, Iowa, 1881; aged 85; died, Nov. 23, 1936, of coronary sclerosis.

**Lewis Rutherford Morris**, New York; Bellevue Hospital Medical College, New York, 1884; aged 74; died, Dec. 9, 1936, of cerebral hemorrhage.

**Wilton Fields Lefavor**, St. Louis; Western Homeopathic College, Cleveland, 1870; aged 90; died, Dec. 9, 1936, of angina pectoris.

**Edwin M. Emrick**, Shamokin, Pa.; Jefferson Medical College of Philadelphia, 1878; aged 81; died, Dec. 5, 1936, of senility.

**Wylie E. Oldham**, Calico Rock, Ark.; College of Physicians and Surgeons, Baltimore, 1885; aged 76; died, Nov. 19, 1936.

**Julia Egbert Hoover**, Cleveland; Cleveland Homeopathic Medical College, Cleveland, 1899; aged 70; died, Dec. 4, 1936.

**Harry Lewis Pelle**, Louisville, Ky.; Louisville and Hospital Medical College, 1908; aged 50; died, Nov. 19, 1936.

**Henry Oscar Marcum**, St. Charles, Ark. (licensed in Arkansas in 1903); aged 67; died, Nov. 22, 1936.

## OPACITY OF CORNEA IN DOGS

*To the Editor:*—Patients brought to me their pet dog, after having visited a number of veterinarians without success, because of a haziness of the cornea of both eyes. This haziness would come and go without incident, but it now has become apparently permanent. The right eye is least affected, but the left is completely grayish white and the poor animal cannot get about. I advised them to put him on a milk and vegetable diet with beef bones and cod liver oil capsules, but no improvement has resulted. Several other dogs of the same litter have been similarly afflicted and that raises the question of heredity, about which my knowledge is very meager so far as dogs are concerned. Can you give me any information on this subject? Please omit name.

M.D., Pennsylvania.

**ANSWER.**—Corneal opacities in dogs are usually due to the traumatism of running through bushes, by which the cornea receives repeated scratches and develops a rather dense scar formation. In the case of the correspondent's dog, apparently a different type of opacity is present. Similar conditions have been observed in laboratory animals both as a congenital defect and as the result of the use of various kinds of drugs, especially large doses of the salicylates and cinchophen. The only treatment that would offer any prospects of success is a liberal diet including plenty of vitamin A, which has already apparently been done, and the avoidance of any drug that might possibly be causing the opacity.

## BED REST IN HEART DISEASE

*To the Editor:*—In my practice I find patients beyond 60 years of age incapacitated by chronic myocardial disease. Their functional capacity, according to the heart committee of the New York Tuberculosis and Health Association, has been thus classified: 1. Patients with organic heart disease, able to carry on ordinary physical activity without discomfort. 2. Patients with organic heart disease, unable to carry on ordinary physical activity without discomfort. (a) Activity slightly limited. (b) Activity greatly limited. 3. Patients with organic heart disease and with symptoms or signs of heart disease when at rest, unable to carry on any physical activity without discomfort. Following this classification, could you inform me in a general way how long these patients should remain in bed? Should they be allowed to get out of bed as soon as possible or should they be kept in bed for a long time? (Please specify number of weeks or months.) Does too much bed rest cause more degeneration of the heart muscle after a certain amount of rest? Please omit name.

M.D., Missouri.

**ANSWER.**—There is no possible way in which one might formulate even a general rule for such cases, even those in group 3. It is entirely a matter of judgment in each case. Rest in bed may be harmful in some cases, and supervised or directed exertion may be beneficial.

## INVOLUTIONAL DEPRESSION AT MENOPAUSE

*To the Editor:*—I would appreciate some diagnostic suggestions with regard to the following case: A woman, aged 42, is sleepy and tired in spite of adequate sleep. She came to me first in June 1934, complaining of irregularity in menstrual periods, irritability, tiredness, insomnia and loss of weight (10 pounds, or 4.5 Kg., in six months). An x-ray examination of the lung was negative at this time. The heart was normal. The blood pressure was 128 systolic, 80 diastolic. There was some pain and tenderness in the region of the appendix. The blood count was normal. No past serious illness had occurred. For the past two months she has been very sleepy at all times. This condition has not changed. No other symptoms exist and the physical examination remains negative.

M.D., New York.

**ANSWER.**—The symptoms described seem to fit into the category of an involutional depression with the corresponding loss of weight that so frequently accompanies this condition. Women at the menopause frequently undergo depressions with insomnia, loss of appetite, loss of weight, and irritability. Lately success has been reported by the use of theelin injections, which substitute for the deficient ovarian secretion. The details are given in articles by Werner and his colleagues.

## TRAUMA AND TUBERCULOSIS OF TESTIS

*To the Editor:*—A man, aged 32, was employed as a wire puller and last January, while pulling a copper bar weighing 300 pounds, was hurt on the testicles. A tuberculous epididymitis and a vesiculitis developed. An old tuberculous condition of the lung became active and later developed into a progressive military tuberculosis. The previous history of the patient is that five years ago he had a tuberculous lesion of one lung, which was cured. Is there, in your opinion, a causal relation between the trauma and the military tuberculosis? Please omit name.

M.D., New York.

**ANSWER.**—It would be difficult to state positively that there was a causal relation between the trauma and the military tuberculosis. All know, only too well, that the same thing may occur in a patient who has not been exposed to trauma.

## Medical Examinations and Licensure

## COMING EXAMINATIONS

## STATE AND TERRITORIAL BOARDS

- ALABAMA: Montgomery, June 29-July 1. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.
- ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Juneau.
- ARKANSAS: *Medical (Regular)*. Little Rock, May 11-12. Sec., Dr. A. S. Buchanan, Prescott. *Medical (Eclectic)*. Little Rock, May 11. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.
- CALIFORNIA: Los Angeles, Feb. 8-11. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.
- CONNECTICUT: *Basic Science*. New Haven, Feb. 13. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven. *Medical (Homeopathic)*. Derby, Feb. 13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven. *Medical (Regular)*. Hartford, March 9-10. *Endorsement*. Hartford, March 23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.
- DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.
- FLORIDA: Jacksonville, June 14-15. Sec., Dr. William M. Rowlett, Box 786, Tampa.
- IDAHO: Boise, April 6. Commissioner of Law Enforcement, Hon. J. L. Balderston, 205 State House, Boise.
- ILLINOIS: Chicago, April 6-8. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.
- INDIANA: Indianapolis, June 22-24. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, 301 State House, Indianapolis.
- KENTUCKY: Louisville, June 9-11. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.
- MAINE: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.
- MARYLAND: *Medical (Regular)*. Baltimore, June 15-18. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homeopathic)*. Baltimore, June 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.
- MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.
- MISSISSIPPI: Jackson, June. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.
- MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.
- NEW HAMPSHIRE: Concord, March 11-12. Sec., Board of Registration in Medicine, Dr. Fred E. Clow, State House, Concord.
- NEW JERSEY: Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.
- NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.
- NORTH CAROLINA: Raleigh, June 21. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.
- OKLAHOMA: Oklahoma City, June 9-10. Sec., Dr. James D. Osborn Jr., Frederick.
- OREGON: *Basic Science*. Portland, March 20. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.
- PUERTO RICO: San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.
- VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.
- VIRGINIA: Richmond, June 17-19. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.
- WEST VIRGINIA: Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.
- WISCONSIN: *Basic Science*. Madison, April 3. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

NATIONAL BOARD OF MEDICAL EXAMINERS  
SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, January 30, page 419.

## Mississippi November Report

Dr. R. N. Whitfield, assistant secretary, Mississippi State Board of Health, reports 5 physicians licensed by reciprocity and 2 physicians licensed by endorsement at the meeting held in Jackson on Nov. 28, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Jenner Medical College, Chicago	(1905)		Illinois
Tulane University of Louisiana School of Medicine	(1934), (1935)		Louisiana
University of Tennessee College of Medicine	(1931), (1934)		Tennessee
School	LICENSED BY ENDORSEMENT	Year Grad.	of
University of Colorado School of Medicine	(1934)		N.B.M.Ex.
Washington University School of Medicine	(1928)		N.B.M.Ex.

## Iowa December Examination

Mr. H. W. Grefe, director, Division of Licensure and Registration, reports the written examination held in Des Moines, Dec. 1-3, 1936. The examination covered 8 subjects and included 100 questions. An average of 75 per cent was required

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### FOOD VALUE OF EGGS

*To the Editor:*—Eggnogs as a source of extra nourishment for patients run into a lot of money by virtue of the cost of eggs. Some textbooks say that raw eggs have little or no food value and are mainly of use as a cathartic and also state that eggs are most assimilable when thoroughly cooked. Will you please give me the present opinion on the food value of raw eggs and mention any articles to which one might refer.

WALTER M. PAMPHILON, M.D., Willard, N. Y.

ANSWER.—The analysis of a whole hen's egg reveals that it contains 13.4 per cent of protein and 10.5 per cent of fat. Hence an average egg weighing 50 Gm. presents 6.78 Gm. of protein and 5.2 Gm. of fat, totaling 75 calories. The mineral constituents of a whole egg are as follows: calcium 68, phosphorus 224, iron 2.52, copper 0.23, magnesium 0.03, chlorine 106, chlorine as sodium chloride 175. The iodine content in parts per billion as established in Ohio on the raw basis is 108 per egg. The vitamin value is as follows: vitamin A, excellent; vitamin B, poor to good; vitamin C, questionably negative; vitamin G, excellent, vitamin D, good. (Bridges Milton: Food and Beverage Analyses, Philadelphia, Lea & Febiger, 1935.) The digestibility of the egg protein and fat has been subjected to much buffeting, but it is well established today that the caloric yield to the human being of raw and soft-cooked eggs is close to the analytic observations.

### PAINFUL BREAST

*To the Editor:*—A white woman, aged 26, who has a child 3 years of age, complains of pain in the right breast and occipital headache. The breast is normal, without inflammation, lumps or swelling. The past history is negative. The breast is well developed and seems to be the same as the left. Physical examination is negative with the exception of slight tenderness in the right lower quadrant of the abdomen and the pelvis (possibly appendix and ovary). What is the probable cause of the pain in the breast and what treatment is recommended? Is it possible for ovarian disease to cause this breast and head pain? Please omit name.

M.D., Kansas.

ANSWER.—There are two possible causes for the pain in the case described. The first is psychic; the second has to do with actual changes in the breast frequently associated with ovarian disturbances. The presence or absence of psychic factors should be established by a careful history. Many patients harboring the fear of cancer complain of painful breasts. The other condition, which is commonly known as "chronic mastitis" but which is actually caused either by an edema of the tissues or by an actual hyperplasia of the ducts and acini or perhaps by a combination of the two, it is difficult to correct. Support of a pendulous breast is of some assistance.

When the cause is mainly psychic, assurance that the patient is not suffering from cancer and that the pain is not related to cancer is of great assistance.

### PERSISTENT SORE THROAT

*To the Editor:*—I have a patient, a World War veteran, who for the past two months has had a pronounced soreness of the left side of his throat. His tonsils have been removed and there are no tags left which could cause this condition. Examination of the throat reveals nothing except that the entire throat is red and congested. There is no enlargement of the cervical glands of the neck, and the vocal cords appear normal. Two weeks ago he had an infected tooth removed but the rest of the teeth appear normal, although they have not been roentgenographed. The patient is worried for fear that he may have the beginning of a malignant condition. How can I relieve his mind on this point? Is there any test for such a condition? What might be the cause of the continuous soreness on one side of the throat while the other side is free from symptoms? Please omit name.

M.D., Michigan.

ANSWER.—It is not stated whether the infected tooth that was removed was on the side on which the throat now is involved, but since the "soreness" was present some time before the dental extraction it does not seem reasonable to ascribe it to the infected tooth. It is possible that a few small deep glands (provided the tooth was on the same side as the inflamed throat) might have been present prior to the extraction and

be a contributing cause to the painful condition. There is a possibility that some neoplasm in its early stage may be present high in the nasopharynx on the affected side or in the pyriform sinus lateral to the larynx. In a word, the patient must be very carefully examined so far as the posterior portion of his nose, his nasopharynx, the beginning of the esophagus, the larynx and the pyriform sinus regions are concerned. Should all these factors, namely, the mouth and other structures named, be eliminated, there is a possibility that some form of neurosis may be present. Perhaps a mild sedative internally and the use of ice pellets in the mouth may have a mitigating action on the "soreness," but a throat examination is most essential.

### HEMOPTYSIS AFTER EVULSION OF PHRENIC NERVE

*To the Editor:*—I have followed up 399 cases of phrenic evulsion during the last three years, 187 on the right right and 212 on the left side. In one case of evulsion of the right phrenic nerve and in seventeen cases of evulsion of the left phrenic nerve, rather severe hemoptysis occurred after the operation, usually in the second week, although most of the patients gave no history of having spit blood at any time previously. Why should phrenic evulsion on the left side lead to hemoptysis? In three cases, in which artificial pneumothorax had been tried and failed prior to the phrenic evulsion, it was induced after the operation to control the bleeding, with success. Is it that the phrenic evulsion released some adhesions and made both the hemoptysis and the induction of artificial pneumothorax possible? If so, why should it happen only on the left side? I shall be thankful for your explanation and for any references, as I could not find any. Please omit name.

M.D., India.

ANSWER.—Hemoptysis following evulsion of the phrenic nerve has not been reported as a frequent occurrence, although attention has been called to it by a number of physicians. The number of cases reported that occur within a week or so following the operation is hardly enough to remove the occurrence from the realm of coincidence. Approximately 35 to 50 per cent of patients with clinical pulmonary tuberculosis have hemoptysis at some time during the course of their disease without any surgery being performed. The phrenic nerve is in apposition with the pleura as it courses through the thorax on each side. Therefore, with involvement of the mediastinal pleura and subjacent lung, adhesions may form. If the nerve sheath becomes adherent, it is possible through tension to produce injury to the adjacent tuberculous lung tissue sufficiently extensive to result in hemoptysis.

Brunner (*Therap. d. Gegenw.* 65:488 [Nov.] 1924) has suggested that in some cases hemoptysis following evulsion of the phrenic nerve may be due to passive congestion of the lung which occurs with the elevation of the diaphragm. At present there is no explanation as to why hemoptysis should have occurred more frequently when the operation was performed on the left side. It is not unusual to make several unsuccessful attempts at artificial pneumothorax to be followed by a successful one. It seems more probable that the success in three cases in which artificial pneumothorax was induced after phrenic evulsion was due to the site of puncture of the parietal pleura rather than to the release of adhesions due to evulsion of the phrenic nerve.

### COLORED SWEAT, OR CHROMIDROSIS

*To the Editor:*—What is the cause of a greenish yellow stain to the vest by perspiration; especially that of the axilla and thorax? Sal soda is used in washing the garments.

H. A. HASKELL, M.D., Windsor, Calif.

ANSWER.—The staining from sweat may be genuine colored sweat, chromidrosis, or pseudochromidrosis. The first condition is rare, occurring usually in neurotic women, the sweat being brown, blue or reddish. Clapton and recently Cole saw green sweat in workers in copper. Blue sweat is usually colorless on appearing at the skin surface and then turns blue, supposedly by oxidation of indican. Genuine chromidrosis is hard to prove, for simulation is often practiced. Spring covered the suspected area with collodion. When the colored sweat reappeared under the collodion, he was assured that the case was a real chromidrosis.

The treatment of chromidrosis depends on finding the cause, which, except in the cases cited of copper workers, is difficult. The female sex, constipation and a neurotic temperament, the etiology usually given, can hardly be called helpful.

Much commoner is pseudochromidrosis, in which the sweat is colored by a growth on the hair of the chest, pubes, inner side of the thigh, the backs of the hands, the axilla, or other portions of the skin. This growth consists of a fungus, *Trichomyces palmellina* or *T. nodosa*, which forms a glue-like mass encasing the hair as a cuff or as nodes on it. This does not form near

whether the increased needs of the rapidly growing child were recognized. The diets obviously were low in milk (less than a pint a day per child), succulent vegetables, fruits and protein; only half of the protein was of animal origin. In view of the American investigations, which are quoted, it seems probable that their incidence of dental improvement might have been still more noteworthy if the basic diets had been more in accordance with the requirements for good nutrition as recognized in this country. Several facts point to the conclusion that the vitamin D served to aid in completing a deficient dietary; in addition to its beneficial effect on the teeth, its use was associated with lessened incidence and severity of colds, similar effects on chilblains (which constitute a source of considerable discomfort in the institutions where the studies were made), and in the general appearance of vitality of the children receiving the vitamin as a supplement.

The experiments seem adequately controlled, the results convincing. While students of nutrition have already accepted the premise the committee has established, the authors point out that the British dental profession has failed to admit its validity.

**Chemical Procedures for Clinical Laboratories.** By Marjorie R. Mattice, A.B., Sc.M., Assistant Professor of Clinical Pathology, New York Post Graduate Medical School of Columbia University. Cloth. Price, \$6.50. Pp. 520, with 92 illustrations. Philadelphia: Lea & Febiger, 1936.

Written almost entirely from the point of view of the more advanced laboratory technician, this book nevertheless incorporates sufficient clinical data to make it interesting to practitioners. It systematically outlines sections on chemical analysis of blood, urine and gastro-intestinal, cerebrospinal and other biologic fluids. Its thoroughness is exemplified by such short but factually rich chapters as those on amniotic hydrocele and seminal fluids. A large appendix contains valuable information on the preparation of many standard solutions—a necessary adjunct to successful laboratory work. Highly interesting to the clinician should be the many tables, graphs and illustrations. The bibliography, though brief, is comprehensive and satisfactory. The clarity of the text is best appreciated in the descriptions of laboratory procedures, which are accompanied by simple drawings. The clinical discussions are appreciably amplified by diagrams which rarely tend to be dogmatic. Occasional clinical shortcomings, as, for example, failure to mention the relationship of the lecithin cholesterol ratio to water balance (as in epilepsy) are easily forgiven because of the excellence in detailing methods of analysis and the pitfalls therein for the unwary. The work is excellent for technicians with a more thorough background, clinicians and clinical laboratories.

**Röntgenatlas der Erkrankungen des Herzens und der Gefässe: Ein Leitfaden für Ärzte.** Von Dr. W. Brednow, Oberarzt der medizinischen Universitäts-Klinik Göttingen. Paper. Price, 10.50 marks. Pp. 155, with 87 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1936.

This is a nicely gotten up atlas of cardiac and vascular diseases, published in atlas form with excellent reproductions of roentgenograms and some nice photographs of modeled specimens of heart lesions. The illustrations include some roentgen kymograms. The normal and the diseased heart are fully illustrated, including insufficiency of the heart muscle and the various valvular and congenital lesions, with a chapter on aortic and peripheral blood vessel disease. It is a valuable publication for radiologists and others interested in heart lesions.

**Atlas der Blutkrankheiten.** Von Dr. Karl Schleich, Chefarzt des Deutschen Krankenhauses in Konstantinopel, und Dr. Albert Alder, Chefarzt der medizinischen Abteilung des Kantonspitals Aarau. Third edition. Half-leather. Price, 50 marks. Pp. 190, with 119 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1936.

This is truly an atlas. The pictures, though highly idealized, are yet sufficiently realistic. The text is badly neglected, and well so, for the reader is certain to neglect it also. It is the illustrations which catch the eye and hold its gaze. They are simple, beautifully colored and attractively arranged but often overcrowded. The authors lay no claim to thoroughness. They state early and clearly that this is an elementary introduction to hematology and refer the reader to other works for descriptive literature. The monophylitic-diphylitic controversy is carefully evaded by merely mentioning the two points of view and apparently siding with neither. The sole purpose is to portray to a beginning student what he could see through his microscope when focused on the usual blood or marrow smear. There is a

short beginning section devoted to simple collecting, staining and technics. This is followed by illustrations of normal and abnormal blood. The classification of disease is based on pathology rather than on etiology and is therefore somewhat confusing. For those who choose to read the text, the simple language offers no obstacles. Students and general practitioners will find this atlas useful.

**One Hour of Medical History. Volume V.** By Benjamin Spector, M.D. Boards. Price, \$2. Pp. 153, with illustrations. Boston: Tufts College Medical School, 1936.

This is the fifth of a series of booklets describing the medical-historical pageants that have become a feature of Tufts College Medical School, where the author has by this means stimulated a real interest in medical history. The present book is largely devoted to the colonial period in American medicine.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Health Insurance: Insanity Attributed to Influenza.**—The defendant insurance company agreed to pay the insured certain specified benefits in event he became disabled from disease. No benefits were payable for disability resulting from insanity. The insured had attacks of influenza in January, April and July 1929, and the insurance company paid him benefits on these occasions. On July 19, 1929, the insured was found praying on the streets and was taken into custody by the police. The following day an insanity inquisition was had, as the result of which the insured was declared insane and committed to an institution. For the disability attributed to the insanity, the company refused to pay benefits. The plaintiff, as guardian for the insured, sued to recover the benefits, contending that the policy covered disability attributed to insanity in case the insanity resulted from a disease covered by the policy. The trial court dismissed the action and the plaintiff appealed to the Supreme Court of Utah.

In excluding from the policy any loss of time or disability resulting from insanity, said the Supreme Court, the policy did not in any manner limit the word "insanity" to any particular type or kind arising from any particular cause. It did not indicate that insanity caused by or resulting from a disease contracted during the policy period was within the policy, but that insanity from congenital, accidental or other causes was outside its operation. The language of the policy taken in its ordinary meaning permits no recovery, in the opinion of the court, for loss or disability because of insanity, whatever the cause of the insanity may have been. The contract of insurance therefore precludes the plaintiff from recovering for disability or loss of time due to the insanity of the insured. The judgment of the trial court was consequently affirmed.—*Moss v. Mutual Ben. Health & Accident Assn. (Utah)*, 56 P. (2d) 1351.

**Compensation of Physicians: Oral Promise by Daughter to Pay for Services Rendered Father.**—The plaintiff, a physician, answered an emergency call from an unknown source to attend a man severely injured in an automobile accident. When he arrived at the scene of the accident, a daughter of the injured man requested him, according to the evidence, to "do everything you can under the sun to see this man is taken care of . . . and what the charges are . . . I will pay for it." The plaintiff did treat the injured man until the following morning, when his services were discontinued at the request of the daughter. The injured man died several days later from the effects of the injury. The plaintiff attempted first to collect his fees from the estate of the deceased. Being unsuccessful, he, about a year after the accident, began sending bills to the deceased's widow. Finally, about a year and a half after the accident, the plaintiff instituted the present suit against the defendant, the daughter of the deceased. The trial court directed a verdict for the defendant and the plaintiff sought a reversal in the Supreme Court of Vermont.

## CHRONIC GONORRHEA

To the Editor:—I have a patient who had gonorrhea three years ago. He states that he was well after treatment of three months, which included sounds, but shreds always persisted. Five weeks ago he commenced to notice a morning drop. My examination revealed a mild prostatitis (from 20 to 25 pus cells to the high power field). The prostate was normal to palpation, but the seminal vesicles were palpable. The urethra did not show strictures or infiltrations. The two glass test revealed numerous shreds in the first glass, but the second was entirely clear. Microscopic examination of the shreds revealed many pus cells but no gonococcus organisms after many repetitions. Treatment has been biweekly seminal vesicle prostatic massages for four weeks with irrigations, and at the present time the prostatic secretion contains only about 8 to 10 pus cells per high power field. After four weeks of massages (last week) I started with a 28 sound and had no difficulty, but after the sound the shreds have increased. The morning drop has never diminished. Irrigations were even stopped in the belief that there was overtreatment. Further treatment will be larger sounds gradually once a week with continued biweekly massages for two more months. Will the morning drop disappear with the advent of the sounds? What will be the fate of the shreds? The man has persisted in drinking and indulgence in sexual intercourse but has not infected any one. Irrigations have been with potassium permanganate 1:8,000 and strong protein silver 2 per cent. Any suggestions, as soon as possible, will be appreciated. Please omit name.

M.D., Illinois.

ANSWER.—The morning drop in itself is of little significance as it is a sign of urethral irritation. In many cases this irritation consists of vigorous daily stripping of the urethra in search of a morning drop, which may only be a drop of mucus which is the normal secretion of the urethra. If any doubt as to the presence of gonococci remains in the mind of either the doctor or the patient, cultures after the method of McLeod (*J. Path. & Bact.* 39:221 [July] 1934) as modified by Thompson (*Am. J. Clin. Path.* 5:313 [July] 1935) are highly reliable.

Urinary shreds are of little significance. They are probably in this case casts of prostatic ducts and may persist for many years. Sometimes if the prostatic ducts are saucerized after the method of Thompson and Cook (*THE JOURNAL*, March 9, 1935, p. 805) the shreds will disappear.

In this case all treatment can be stopped and the patient instructed to refrain from stripping the urethra and from alcohol. If symptoms persist, a urethroscopic examination should be done. The amount of prostatitis should be rechecked in two months.

## TUBERCULOSIS IN DOMESTIC ANIMALS

To the Editor:—Are dogs and cats susceptible to tuberculosis? If so, might the disease in either of these animals take a chronic pulmonary form with cough and the expectoration of sputum containing tubercle bacilli? Please omit name and address.

M.D., Colorado.

ANSWER.—Dogs and cats contract tuberculosis from both the human and the bovine type of tubercle bacilli. However, the dog manifests a strong resistance against the avian type of tubercle bacillus, as shown by the extensive experiments of Feldman (*J. Am. Vet. M. A.* 76:399 [March] 1930; *Am. J. Path.* 7:147 [March] 1931). He introduced tubercle bacilli of the avian type by various methods, such as inoculation and feeding of tuberculous chickens, into the bodies of fifty-four dogs. At the end of a year in those animals which had been inoculated intraperitoneally or intrabronchially there could be found no evidence of tuberculosis. Of ten dogs with tubercle bacilli introduced directly into the blood stream, one developed tuberculosis. Among thirty dogs fed on tuberculous material, microscopic lesions suggestive of tuberculosis were found in only a few. It was only when tubercle bacilli of the avian type were introduced directly into the cerebral tissues that all animals developed tuberculous lesions that were fatal.

In Europe, tuberculosis caused by the human and bovine types of tubercle bacilli is estimated to be present in as many as 5 per cent of the dogs. Petit (*Rec. de méd. vét.*, 1900, pp. 342, 405; 1901, pp. 5, 85, 162; *Presse méd.*, Aug. 12, 1925, p. 1082) reported that from 1900 to 1904 in France tuberculosis among dogs increased from 4.57 per cent to 9.11 per cent. Douville (*Rev. gén. de méd. vét.*, May 1, 1914) found approximately 4 per cent of the dogs tuberculous and points out that race and age of dogs has no influence on the disease. However, he calls attention to the sources of infection, such as public drinking places and cafés, where tuberculous persons expectorate on the floors and the dogs consume the sputum. In fact, among 100 tuberculous dogs, fifty-one belonged to the proprietors of such places, while twenty-three had for a long time been in contact with persons suffering from tuberculosis. Douville has pointed out that approximately 1 per cent of the cats of large cities are suffering from tuberculosis. In dogs the human type of tubercle

bacillus is found more frequently than the bovine type, whereas in cats the bovine type is more frequently seen, probably because of their greater consumption of milk.

In this country not many figures are available, but in one group of postmortem examinations, consisting of 1,548 dogs, tuberculosis was found in approximately 1 per cent. The lungs are frequently attacked and this, of course, makes the tuberculous dog or cat an unsafe associate for both adults and children.

## TREATMENT OF CONGENITAL SYPHILIS

To the Editor:—I have under my care and treatment a patient (divorced) who has 4 plus Kolmer, Wassermann and Kline reactions. A blood test of her 10 year old boy gave Kolmer and Wassermann negative reactions but a 2 plus positive Kline reaction. What prognosis can I give the mother and what would be the best treatment? Please omit name.

M.D., Minnesota.

ANSWER.—Even though the child's mother has syphilis, a single 2 plus Kline reaction is not sufficient evidence on which to base a diagnosis of congenital syphilis. Not only should the blood tests be repeated, but other procedures such as the Kahn and Hinton technics should be employed as a check against the sensitive Kline technic. It is possible for a child with congenital syphilis to reach the age of 10 without manifesting any evidence of the disease except a weakly positive flocculation test. On the other hand, it would seem unwise as well as definitely unwarranted to make a diagnosis of congenital syphilis on such slim evidence as is presented by this patient. If, on repetition, the tests are found to be positive, the child should be treated by being given a series of courses of arsphenamine or neoarsphenamine and a bismuth preparation. If the spinal fluid is found to be negative, the prognosis is more favorable. It does not seem advisable to attempt to outline in this limited space a complete course of treatment for a child with congenital syphilis, and for such information the inquirer is referred to one of the newly published textbooks, such as the one by Stokes or the volume more recently prepared by Moore.

## URINATION DURING INTERCOURSE

To the Editor:—A healthy woman, aged 26 (nulliparous) complains of inability to retain urine when having intercourse with her husband. This is true even when the bladder has been recently emptied. The sensation is quite pleasurable at the time of micturition. Is this unusual or pathologic? Please omit name and address.

M.D., Massachusetts.

ANSWER.—The condition is unusual and pathologic. It is necessary to examine the urethra, as at times there are polypi or other abnormal conditions, so that the pressure of the penis against this part during connection gives the impulse to urination. It must be noted that the urethra in the female is an important source of erotic sensation, for which reason girls and women who masturbate often do so by sticking a hairpin, pencil or similar object into the urethra. In case nothing pathologic (even a mere congestion) is found in the urethra or bladder neck, the condition must be considered a neurosis and treated accordingly.

## ELECTROTHERAPY FOR CORNEAL ULCERS

To the Editor:—Please indicate the status of electrotherapy with reference to corneal ulcers, mentioning the type of apparatus used in electrocoagulation, fulguration, cauterization or what not.

LUCIEN BROWN, M.D., Gadsden, Ala.

ANSWER.—The following procedures of electrotherapy have gained fairly universal recognition among ophthalmologists for use in corneal ulcers:

Ionization with a solution of zinc salt under 1.5 to 3 milliamperes of current has been most favorably reported on and in some clinics is standard practice. Any standard apparatus is used. Ionization with atropine sulfate is also used in case of poor pupillary dilatation.

Cauterization of a corneal ulcer is a standard procedure. Any cautery tip that can be brought to a cherry red heat by electrical means will suffice. Cauterization or, rather, baking with a lower degree of regulated heat over a longer period of time, such as with the Shahan thermophore, is an accepted measure.

Cauterization with diathermy is too dangerous a procedure. Short wave diathermy for the localized elevation of temperature is an accepted method that has proved satisfactory. Any good short wave diathermy apparatus or induction apparatus will suffice.

Fulguration is too dangerous.

plained of when the pressure reaches 100 mm. of water. Amyl nitrite and glyceryl trinitrate relieve the intraductal pressure produced by morphine.

Dilaudid, pantopon (a mixture of opium and alkaloids) and codeine produce effects similar to morphine. Glyceryl trinitrate  $\frac{1}{100}$  grain (0.00065 Gm.), the variety for hypodermic use, placed under the tongue, after a period of three minutes reduces intrabiliary pressure and relieves biliary colic. If the pain has been brought on by morphine, the glyceryl trinitrate relieves it for one hour. Theophylline with ethylene diamine, when given intravenously, relaxes spasm of the sphincter of Oddi.

Drugs believed to increase the activity of smooth muscle of the gastro-intestinal tract, such as acetylcholine, physostigmine and ergotamine tartrate, did not produce demonstrable spasm or relaxation of the sphincter of Oddi. The drugs commonly believed to have a relaxing effect on smooth muscle, such as atropine, scopolamine, papaverine hydrochloride and calcium chloride, as well as drugs known to have a relaxing action on blood vessels, such as alcohol, histamine and muscle adenosine phosphate, did not produce evidence of relaxation of the sphincter of Oddi nor did they produce spasm.

#### DISCUSSION

DR. K. K. CHEN, Indianapolis: May I ask the authors whether they tried papaverine?

DR. L. N. KATZ, Chicago: Did the authors note any correlation between the threshold of the pain response to pressure and the clinical composition of the bile present in the gallbladder? Did they note whether there was any correlation between the threshold of the pain on pressure and the presence of inflammatory processes in the gallbladder? Such variability might be expected since one is dealing here with sense organs that are responsive to threshold stimuli. The threshold might therefore be modified by clinical agents or inflammatory processes.

DR. P. K. KNOEFEL, Louisville, Ky.: Can pantopon produce the same effect as morphine?

DR. G. O. BROUN, St. Louis: What about dilaudid?

DR. CLYDE LEEPER, Cleveland: Is there any relation between pain of such origin and cardiac pain since both are relieved by glyceryl trinitrate? I should like to ask about the distribution of this pain and whether it simulates cardiac pain.

DR. ARTHUR MIRSKY, Chicago: I should like to ask whether a spasm of the sphincter is observed sufficiently long to produce an obstruction of bile and jaundice.

DR. WALTMAN WALTERS, Rochester, Minn.: Replying to the question relative to the effect of papaverine, pantopon and dilaudid on the sphincter of Oddi: In the cases which we have studied papaverine has had no effect on the relaxation of the sphincter of Oddi, while dilaudid, pantopon and codeine produced effects similar to those of morphine. Replying to the question as to differentiation between the attacks of pain attributable to coronary disease and those attributable to spasm of the sphincter of Oddi, it can be stated that in the cases in which we carried out these studies of intraductal pressure we have demonstrated not alone by studies of pressure but also by roentgenologic visualization of the common bile duct that pain occurs when there is a spasm of the sphincter which increases the pressure within the common bile duct and fills many of the finer radicles of the intrahepatic ducts. This was demonstrated in one of the illustrations which we presented. With the administration of amyl nitrite and glyceryl trinitrate, spasm of the sphincter decreases and fluid can be seen to leave the common duct and enter the duodenum with the resulting decrease in intraductal pressure. This, I think, is definite evidence that the pain in these cases has been the result of spasm of the sphincter of Oddi or of the lower end of the duct and not the result of cardiac disease. I do not know of any case in which spasmodic obstruction of the sphincter unassociated with other lesions of the duct or pancreas has produced jaundice.

#### Recovery from Extensive Cirrhosis of Liver

DRS. JESSE L. BOLLMAN and ALBERT M. SNELL, Rochester, Minn.: Cirrhosis of the liver was produced in experimental animals by carbon tetrachloride. When ascites of sufficient degree to require frequent paracentesis was present, biopsy disclosed extreme degrees of cirrhosis. Daily intravenous injections

of dextrose and repeated paracentesis over periods of several weeks were followed by diminution of the volume of ascitic fluid and improvement in the condition of the animals. Functional tests and biopsy of the liver indicate restoration of that organ to a practically normal state. Histories of patients who have portal cirrhosis and who give evidence of marked clinical improvement following similar treatment are presented. The clinical and experimental results indicate that the long continued intravenous administration of dextrose may bring about regeneration of the liver in some instances even after ascites and definite hepatic insufficiency have developed.

#### DISCUSSION

DR. SAMUEL SOSKIN, Chicago: My own results concerning the value of dextrose in such conditions agree most thoroughly with the results reported by the authors. I should like to ask what type of diet their animals were fed during the period in which they were being intoxicated and their livers were deteriorating.

DR. ROBERT W. KEETON, Chicago: What was the daily dose of dextrose in this patient?

DR. WALTER L. PALMER, Chicago: I should like to ask whether or not the authors think it is necessary to give intravenous dextrose provided the patient is able to take dextrose by mouth. I am aware that many of these patients are not able to take dextrose by mouth for a number of days. It may be worth while to recall the story told by Dr. Joseph L. Miller of a patient who came to the Cook County Hospital twenty years ago with slight jaundice and ascites. One night the patient had a vision in which an angel came and advised him to eat a pound of sugar a day. He ate a pound a day and he got well. Twenty years later the ascites recurred.

DR. GEORGE E. WAKERLIN, Louisville, Ky.: Were blood studies made on these dogs? Is there any advantage in giving carbon tetrachloride by inhalation rather than by mouth?

DR. LOUIS LEITER, Chicago: Would the administration of dextrose be considered a specific measure for the regeneration of liver cells or for the purpose of furnishing calories to animals or persons not able to eat?

DR. JESSE L. BOLLMAN, Rochester, Minn.: With reference to Dr. Wakerlin's question concerning the diet of our animals and about the method of carbon tetrachloride administration, the following may be said: In these experiments the animals were maintained on a diet completely adequate for their basal requirement with an addition of carbohydrate to cover their energy needs. In other experiments we have succeeded in producing cirrhosis on diets rich in fat or diets rich in protein. However, under such circumstances the administration of carbon tetrachloride frequently produces extensive acute necrosis of the liver with fatal termination. Cirrhosis develops as a result of frequent breakdown and repair. The damage to the liver must be sufficient to stimulate cellular regeneration and at the same time remain sublethal, so that the process may be repeated many times. The advantage of administering carbon tetrachloride by inhalation is that by producing anesthesia for a definite period of time we have standardized one physiologic effect of the drug and the effects on the liver seem to be more comparable. When the drug is given by mouth, the extent of the lesions of the liver vary greatly. I think that the variations are due to differences in the rate of absorption which we have been unable to overcome. Blood studies of cirrhotic animals at the stage of ascites formation show that there is a decrease in the serum albumin and usually some increase in the serum globulin. A macrocytic type of anemia is frequently, although not always, found to be present at this time.

DR. ALBERT M. SNELL, Rochester, Minn.: In answer to Dr. Keeton's question, we gave from 100 to 200 Gm. of dextrose daily. Dr. Palmer and Dr. Leiter raise the question whether the same effects could not be obtained by dietary means alone. This is doubtful, since a patient in this condition could hardly take a sufficiently high carbohydrate diet to accomplish much; this is as true of the dog with experimental cirrhosis as it is of patients with comparable conditions. Perhaps the maintenance of a sufficient intake of calories and fluid is all that is necessary, although on the whole it seems that dextrose given intravenously does have some specific value.

## PERIOSTITIS AND OSTEOMYELITIS

*To the Editor:*—A man, aged 40, had a severe contusion over the left tibia about twenty years ago. A periostitis developed and the leg was incised and the bone scraped. This was repeated several times until healing took place. At the present time the slightest bump to this area causes a breakdown of the tissue, which will not heal readily. Small pieces of bone protrude through the wound and bone has to be removed. His last injury was in December, and the wounds still drain a serous material. His general condition is good and x-ray examination of the bone shows no evidence of destruction. Any suggestions as to what is taking place and some means of helping to heal the injured areas will be deeply appreciated. Please omit name.

M.D., Ohio.

**ANSWER.**—The history of this patient, aged 40, with an injury involving the tibia of twenty years' duration, complicated by periostitis, repeated breaking down of the wound on slight injury, and several operations, is not unusual. Frequently following periostitis and osteomyelitis the tissues over the shin are left so thin and the vascular supply is so deficient that they permit breaking down of the scar tissue on the slightest provocation. When these injuries are more severe and infection is present, fragments of bone may be discharged. In long standing cases of this type it is always well to exclude syphilis. Occasionally ulcers develop and when present for long periods may become malignant (epithelioma).

It would be advisable for the patient to wear some form of a guard to protect the leg from injury. Surgical treatment, in an effort to transplant healthy skin in the affected area, is of value in giving such patients relief.

## OSTEO-ARTHRITIS

*To the Editor:*—A white man, aged 60, robust, had an automobile accident in which he turned over in the car. Sometime later he complained of some pains in his back. This occurred about fifteen years ago. About ten years ago he had a peritonsillar abscess, which was promptly drained. Two years ago he had malaria, at which time he had a temperature of 104 and complained of severe pains in his back. Since then he has complained more or less of these. The last two weeks he has suffered severe pains on moving and I advised him to have an x-ray examination of his lumbar spine. This revealed marked osteo-arthritis of the lumbar and thoracic spine, spur formation with bridging and a beginning ankylosing spondylitis, and a phlebolith on the left but no opaque stones in the biliary tract. Kindly omit name.

M.D., Tennessee.

**ANSWER.**—Trauma may be a factor in the development of osteo-arthritis. Focal infection, while rarely of primary etiologic importance, may be a contributory factor. After spur formation with bridging and beginning ankylosis, complete anatomic or functional recovery cannot be hoped for. Rest, either complete as in a cast or partial as obtained by ambulatory support, may be expected to add to the patient's comfort, while activity tends to aggravate the symptoms. From four to six weeks' rest in bed either in a plaster cast or on a Bradford frame is advisable if the patient will agree to it. This should be followed by the application of a good back brace, which maintains the spine in the best possible position for function so that if or when ankylosis does occur, deformity may at least be minimized. Heat and massage may be soothing, but salicylates are of little value as a rule. Vaccine injections or solutions containing sulfur compounds or gold salts offer little hope for correcting or alleviating a situation in which osseous changes have become as marked as those described.

## BLOOD TRANSFUSION IN INFANCY

*To the Editor:*—Kindly send me information as to the site of injection usually preferred in a blood transfusion in an infant 3 weeks of age; also the site most frequently used in an infant, and whether the median basilic or cephalic vein is ever or rarely used for a blood transfusion in an infant 3 weeks old. Is the median basilic vein in a 3 weeks old infant large enough to admit a 20 gage needle for a blood transfusion? If this is to be published, kindly withhold name.

M.D., New York.

**ANSWER.**—The veins most frequently used for blood transfusion in a 3 weeks old infant are those of the arm, ankle and scalp, and the external jugular vein. The longitudinal sinus has also been used for intravenous injections. The sites most frequently used when the needle is inserted without exposing the vein by incision are the veins in the cubital fossae, the external jugulars and the scalp veins. If incision and exposure of the vein are abused, an ankle vein, preferably the saphena magna, which may be found just anterior to the internal malleolus, is the site of preference.

Number 18 or 20 gage needles are recommended, though for small veins a needle as small as gage 26 may be used successfully. As a 3 weeks old infant may vary in weight from 5 to 10 pounds (2.3 to 4.5 Kg.) with correspondingly smaller or larger veins, it would be necessary to judge the gage of the needle for each individual case.

## CORRECTION OF FACIAL DEFECT

*To the Editor:*—A young woman has a rather unsightly hollow on her forehead just above the root of the nose between the eyebrows. An experimental injection of about 1 cc. of saline solution subcutaneously makes a marked improvement in her appearance. Can you advise me of anything that might be injected to remain permanently? I thought of heavy mineral oil, of wax, and of making a small incision through the eyebrow and inserting a little silver plate. Can you help me?

M.D., British Columbia.

**ANSWER.**—The introduction of any foreign material for cosmetic correction is unsound and dangerous. This is particularly true of so-called fillers that contain a paraffin base.

The correction of this defect may be simply and permanently accomplished with a dermal graft. A three-eighths inch incision is made along the upper mesial line of the eyebrow and the skin over the defect undermined. The required bit of skin may be removed from the abdomen, prepared in the usual manner and introduced through this small incision. A pressure bandage is applied for several days.

## ROSACEA-LIKE TUBERCULID

*To the Editor:*—I have been troubled with a pustular eruption on the alae of the nose for the past four years. Small pustules appear on either side every five to seven days. It has been diagnosed as a seborrheic dermatitis by several dermatologists. Salicylic acid ointments, sulfur ointments, solution of sulfurated lime, lotio alba, vaccine, ultraviolet rays and ten doses of x-rays were given with little effect. The x-ray treatment was given by competent men at the University of Illinois Research Hospital about two years ago with the purpose of atrophying the seborrheic glands. Are there any suggestions which you may offer? Do you think it is worth while to have another series of x-rays to atrophy the glands? There is a pitting present with some rosacea. I would appreciate any suggestion which you might offer. Kindly omit name.

M.D., Washington.

**ANSWER.**—From the statement made that there are pustules, together with pitting and some rosacea, it would seem appropriate to consider the possibility of the rosacea-like tuberculid. This condition is resistant to the ordinary treatment outlined for seborrheic dermatitis, the diagnosis offered in this case. Roentgen rays given to the extent of producing atrophy of the glands would make undesirable changes in the skin and its vessels. Further suggestions about the treatment without more definite information as to the exact condition would not be of value.

## LOSS OF PUBIC HAIR

*To the Editor:*—Will you kindly advise me as to the cause, prognosis and treatment for loss of pubic hair? The patient is a white man, aged 32, apparently healthy. Onset occurred seven years ago, with practically total loss of the pubic hair at present. There is no history of venereal disease. The Wassermann reaction is negative. The distribution of hair elsewhere is normal, with a heavy growth on the face and scalp. The patient was a very heavy cigar smoker for years. He is somewhat obese, with no definite abnormalities as to the distribution of fat. Glandular therapy both orally and parenterally has been unsuccessful; pituitary, thyroid and orchic substance has been used. X-ray examination of the sella turcica reveals a slight narrowing (if any) with no bony erosion. Please omit name and address.

M.D., New York.

**ANSWER.**—Without information as to the onset and course of this alopecia, the distribution of the remaining hair, and the presence or absence of scars or inflammatory areas, a diagnosis is impossible.

If scars are present, tertiary syphilis is most likely, in spite of the negative serologic reaction at present. If the skin is apparently normal in texture and color, alopecia arcata is most likely. The only way to arrive at a diagnosis is an expert examination. Consultation with a dermatologist is advised.

## SCARIFICATION WITH COAL DUST

*To the Editor:*—In this region, where there is a lot of coal mining, the traumatic abrasions and lacerations caused by injuries with coal result in quite prominent blue scarification. These scars, when occurring on the exposed parts of the body, result in quite serious complications from a cosmetic and compensation standpoint. What is the most effective means of treating such injuries with a view to preventing these pigmented scars? What is the best treatment of these scars after they have formed? Kindly omit name.

M.D., Pennsylvania.

**ANSWER.**—Abrasions and lacerations caused by coal or other types of carbon should be curetted thoroughly before sutures are inserted or the wound allowed to heal. The disfiguring areas of carbon deposit not removed at the time of the injury are most satisfactorily removed by plastic surgery. A few of them may be removed by tattooing first with 50 per cent tannic acid solution and then with silver nitrate. It requires some time for the resulting eschar to separate, leaving in successful cases a white superficial scar.

DR. G. K. FENN, Chicago: I should like to ask Dr. Myers why he gives his single dose of protamine zinc insulin at 7 o'clock in the morning when the maximum hypoglycemia occurs about twenty-two hours later. If the patient is to have a hypoglycemic reaction it would seem desirable to have it while he is awake.

DR. GORDON B. MYERS, Detroit: With reference to Dr. Rickett's discussion, we have also increased the dose of protamine zinc insulin in the presence of acute infection of the upper respiratory tract. It has sometimes been necessary to give a small dose of regular insulin in the morning as a supplement. With reference to Dr. Fenn's question, our choice of a 7 a. m. injection time for protamine zinc insulin was based on a trial conducted on five patients. These five patients received a single daily dose successively at 7 a. m. and 6, 8 and 11 p. m. The blood sugar was best controlled when the injection was given at 7 a. m. It was fairly well controlled by a single dose at 11 p. m. but poorly controlled with injections at 6 or 8 p. m.

DR. RANDALL G. SPRAGUE, Rochester, Minn.: We found it true that the requirement of protamine insulin is increased in the presence of infection; however, it is impossible to say that the increase is out of proportion to that which is observed when regular insulin is used alone. Probably the best procedure in the presence of infection is to leave the dose of protamine insulin unchanged and to meet the increased requirement by additions of regular insulin. With regard to the use of protamine insulin alone in diabetic acidosis, Dr. Rabinowitch has reported good results with the zinc preparation in two cases. Probably such a practice should not yet be adopted generally because it may be very dangerous owing to the slow insulin action. We have used protamine insulin as a supplement to regular insulin in the treatment of acidosis, and we have the impression that it may facilitate control of the condition; however, for the present we feel that the chief reliance should be placed on regular insulin.

#### Observations on "Prediabetes"

DR. HUGO R. RONY, Chicago: Twenty cases of obesity associated with "prediabetes"—very low sugar tolerance—were observed in the clinic for from one to nine years. During this time repeated dextrose tolerance tests were made following varied dietary regimens. The purpose of this study was (a) to find out when and under what conditions diabetes would develop in such cases and (b) to observe the effect of certain dietary factors on the sugar tolerance in this syndrome.

(a) None of the patients developed diabetes. The dextrose tolerance increased in the majority of cases, including some in which the weight remained the same and one in which the weight increased. Persistent decrease of dextrose tolerance was not observed in any case. Accordingly, direct observation does not support the current idea that low sugar tolerance in obesity is a precursor to diabetes.

(b) Obese persons with low dextrose tolerance respond to low carbohydrate diet or fasting with immediate increase of dextrose tolerance; high carbohydrate diet promptly depresses the dextrose tolerance. This is the opposite of what is known to occur in normal persons. Evidence is presented suggesting that this difference between obese and normal persons is due to the capacity of the fat depots to absorb large amounts of dextrose from the blood when dextrose is ingested after a period of undernutrition.

#### DISCUSSION

DR. ELMER L. SEYRINGHAUS, Madison, Wis.: I should like to ask Dr. Rony whether he will state his definition of prediabetes. According to the conventional sugar tolerance tests, these cases he has illustrated would be diagnosed as diabetes and would be classified as of the nonprogressive type. Perhaps the definition he is using will clarify the problem.

DR. HUGO R. RONY, Chicago: The most important point in the diagnosis of diabetes is, according to Joslin, the elevation of the fasting blood sugar. In a number of our cases the fasting blood sugar was below 120 mg. per hundred cubic centimeters; in no case was it above 140 mg. Furthermore, these cases showed no clinical signs or symptoms of diabetes, such as spontaneous loss of weight, polydipsia or polyuria. The term "prediabetes" has been recommended by some authors because they thought that these patients eventually develop

manifest diabetes—a belief which is not supported by actual observation. The underlying metabolic disturbance in such cases is probably quite different from that which is manifested by clinical diabetes.

#### "Insulin Resistance" and Related Conditions

DRS. SAMUEL SOSKIN, M. DAVID ALLWEISS and I. ARTHUR MIRSKY, Chicago: While the decreased carbohydrate tolerance in toxic conditions has often been ascribed to pancreatic injury, the relative ineffectiveness of administered insulin under the same conditions suggests some other organ or tissue as the site of the toxic disturbance. Our recent studies, in experimentally toxic dogs, have shown that the liver is the chief organ involved. The hepatic disturbance consists of two distinct phases: (1) impairment of the homeostatic blood sugar regulating mechanism and (2) a decreased ability to store glycogen of endogenous origin. This work offers a clinically useful conception of "insulin resistance," "insulin sensitivity" and certain cases of so-called hyperinsulinism. It also offers a rational approach to the therapy of these conditions.

#### DISCUSSION

DR. CECIL STRIKER, Cincinnati: I should like to ask whether any of these dogs developed diabetes in the presence of cirrhosis of the liver.

DR. ADOLPH SACHS, Omaha: I should like to ask whether Dr. Soskin has had any experience with insulin resistance in cases of hemochromatosis and, if so, does he think that the amount of liver damage bears any relationship to the insulin resistance?

DR. WALTER L. PALMER, Chicago: I should like to ask how much direct evidence of liver damage there is in these patients who are insulin resistant.

DR. W. A. THOMAS, Chicago: It is interesting to note in a study of the toxemias of pregnancy in the early stages in which there is likely to be a glycosuria that there is evidence of liver damage. In the last trimester, in which the toxemias are more severe, there will be low blood sugar and lowered liver function. So there are two stages of irritability of the liver.

DR. SAMUEL SOSKIN, Chicago: With regard to what might be called "toxic diabetes" as opposed to true diabetes, it is difficult to distinguish clinically between the two, in the present state of our knowledge. The liver is the effector organ in diabetes of whatever origin. The end results are therefore very similar. In the analogy in which I compared the homeostatic liver mechanism to a thermostat-furnace mechanism, I pointed out that anything which would prevent the thermostat from responding to a rise in room temperature would allow an overaction of the furnace and would lead to a rise in room temperature. Likewise any disturbance, whether toxic or hormonal, which prevents the liver from responding normally to a hyperglycemia may result in a similar diabetic state. There are certain things, such as the presence of other evidence of liver dysfunction, which help in the diagnosis of a "toxic diabetes." We have observed cases in which there was such evidence, as shown by jaundice and abnormal responses to liver function tests. As to the relation of hemochromatosis to insulin resistance: what one finds in any form of liver damage depends on the degree of damage present. We have previously described a characteristic cycle of events as regards the dextrose tolerance curve in a progressive toxic liver injury. In today's communication we have shown that the same cycle of events occurs as regards the response to insulin administration, once the factor of endogenous glycogen formation has been taken into account. Thus any isolated test of carbohydrate tolerance or insulin sensitivity is difficult to interpret. One must know something of the course of events. It is important to consider the duration of the condition and the presence of other evidence of liver damage. For example, we showed the records of toxic animals, in which the dextrose tolerance curves and the response to injected insulin became quite normal. This did not mean that these animals were improving, for they were obviously getting worse and eventually died. A similar occurrence has been reported in patients with diabetes and liver cirrhosis, in whom the diabetes subsided as the cirrhosis progressed toward a fatal termination.

## Book Notices

**Dental Pharmacology and Therapeutics.** By J. R. Blayney, B.S., D.D.S., M.S., Professor of Dental Pathology and Therapeutics, University of Illinois College of Dentistry. Second edition. Cloth. Price, \$4. Pp. 340, with 25 illustrations. St. Louis: C. V. Mosby Company, 1936.

This edition has been required principally by the publication of the United States Pharmacopeia XI. The text is divided into three parts and considerable orderliness and system prevail throughout. Part I covers such general considerations as the principle of action of drugs, methods of administration, prescription writing, tables of solubilities, and average doses. The author recommends the use of English exclusively in prescription writing, his only deviation from this being the employment of some common Latin abbreviations. The book, therefore, contains no section on medical Latin. Following each main division in part I the author presents a number of problems which add much to the value of this work to the student. Part II is devoted to the consideration of drugs. These are arranged according to their chief dental uses, but the usual pharmacologic grouping has been largely maintained. The study of each important group is introduced by a discussion of such topics as mode of action and standardization of efficiency. These preliminary statements are in many instances rather extensive and interestingly presented and give valuable information. Of special value in this section are many excellent illustrations. The author does not attempt to present the extensive discussion of pharmacology which is necessary for the physician and in considering those drugs which are little used. For example, in the discussion of diuretics, dextrose and the mercurials are not even mentioned. It might be suggested that he has been a little dogmatic at times in apparently presenting, as established facts, theories that are still controversial. More moderation might also have been shown in the handling of other phases of his subject. For example, in outlining the danger of the barbiturates he states that when any of these are used daily "we may expect to find skin eruptions, injury to the kidneys, ataxia or aphasia." Practical experience in the long continued use of phenobarbital in such conditions as epilepsy does not justify this statement. Part III contains a well selected series of laboratory exercises which should be of much interest and value to the dental student. The printing is good and it is a relief to find the large type and liberal spacing which lend themselves to easy reading. Considered as a whole, this is an excellent presentation of the subject for the purpose for which the volume is intended. It naturally contains much that would be of interest to the practitioner in medicine and, as it is comparatively small, it would serve as a useful review to those physicians who have not the time or inclination to undertake a more extensive treatise.

**Being Born.** By Frances Bruce Strain. Cloth. Price, \$1.50. Pp. 144, with illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1936.

This is a book to arouse enthusiasm. It tells everything that a young person could wish to know about sex. It uses correct scientific terminology. It is devoid of emotionalism and sentimentality. It is clear and concise. The "road maps" showing the routes by which the ovum and the sperm make the necessary contact are diagrammatic, clear and easily followed. The photographs showing the similarity of various species in the early fetal stage and the serial photographs of the human fetus in various developmental stages are excellent, as are the window

silhouettes showing the gravid uterus in its relationship to the mother's body. The use of animals to illustrate certain points is interesting because the author reverses the usual order. Instead of describing the procreation processes of amebas, fish, frogs, turtles, birds, mammals and finally man, she starts right in and talks about her principal topic, using the animals as illustrative and comparative sidelights. The method is effective. Especially valuable is the chapter on heredity, out of which comes so easily the next step, the lesson of continence and monogamy. There is no preaching in this book, and therein lies its power. While it is unemotional and scientific, it is not cold, but friendly and personal. Lovely photographs of statues showing the beautiful nude body of a young boy and of a young girl have been chosen with extraordinarily good taste to express the beauty and grace of the body with a fine candor which subtly enhances the spirit of the text. The introduction, written for parents, is separate; parents are advised to remove this and the jacket and to give the book as a gift of which the owner may be proud. Throughout, the work shows profound thought, meticulous care, and a sympathetic understanding of youth as well as of the psychology of the learning process. Altogether, it is an admirable work.

**The Influence of Diet on Caries in Children's Teeth (Final Report).** By The Committee for the Investigation of Dental Disease (Assisted by Alan Deverall and Mabel Reynolds). Medical Research Council, Special Report Series, No. 211. Paper. Price, 2s. Pp. 137, with 8 illustrations. London: His Majesty's Stationery Office, 1936.

The report summarizes the conclusions of the Committee on Dental Disease, appointed by the British Medical Research Council to test the validity of the theory, based on Mellanby's earlier work, that the nutritional condition of the body is a dominant factor in determining the structure of teeth and their resistance to decay. Specifically, the study was confined to the effect on the incidence of dental decay of the administration of vitamin D, in the form of either cod liver oil or viosterol. The children studied were inmates of three orphanages in the vicinity of Birmingham. About 250 children were included in the survey; one study continued over a period of three years, another for two and one-half years. In addition to detailed dental records, data were obtained as to the level of general health and bony deformities such as are produced by rickets. The dental examination included the study of the surface structure of the teeth, caries, alinement and occlusion, and condition of the gums. Activity of caries was gaged from the "texture" of the exposed dentin; if soft enough to permit entry of the exploring fine in any degree, activity was designated. As supplements to the "basic diet," the following were offered daily to each child, a different supplement being used in each of the three orphanages: (1) from 1 to 1½ ounces of syrup; (2) from 1 to 1½ tablespoonfuls of olive oil; (3) from 1 to 1½ tablespoonfuls of cod liver oil. The exact amount of each was proportional to the age of the child. In the second survey, half of the group receiving olive oil received oil containing viosterol. The cod liver oil had a vitamin D equivalence of from 15 to 150 international units per cubic centimeter, the usual variations being from 50 to 100; the viosterol solution, given in volume equivalent to that of cod liver oil, contained about 625 units per cubic centimeter. A subsidiary third study on the effect of added vitamin D on the structure of the teeth of young children failed in its objective because of difficulties in administration. The data are analyzed in great detail, due regard being given to possible secondary factors in the studies. In summary, the following statement expresses the committee's interpretation of the results observed: "The investigations described in this report show conclusively that a relatively high vitamin D content of the food can do much to diminish the incidence of caries if the vitamin is given during the development of the teeth; that a beneficial effect may be obtained if the vitamin is given at a fairly late stage of development; and that even when it is given after the eruption of the teeth, the onset and spread of caries is delayed."

It is interesting to analyze the nature of the basic diets used in the three orphanages, since the authors state that "the diets . . . are satisfactory according to accepted standards and are certainly better than the diets obtainable by the majority of the children . . . of the community." The data are offered in terms of allowance per "man" daily, with no reference to

reviewed merely presented their cases briefly without discussing the phenomenon at any length. The authors had the opportunity to observe a patient in whom bilateral zoster developed while he was in the hospital for cutaneous, osseous and pulmonary tuberculosis. The study gives no reason to doubt the theory that herpes zoster is caused by a virus. Among the possible predisposing factors may be listed "rheumatism and heart disease," syphilis, malaria or ingestion of quinine, neurosyphilis, acute arsenic poisoning, diphtheria or administration of diphtheria antitoxin, sunburn and tuberculosis of the spine. In the majority of cases no such factors could be found. The old theory that bilateral zoster is usually associated with syphilis or with the administration of arsenic is not supported by the series reviewed. A relationship between bilateral herpes zoster and varicella could not be established in any case. The severity of the eruption and of the subjective symptoms was no greater in patients with bilateral than in those with unilateral zoster. Recovery from bilateral zoster is about as rapid as that from unilateral zona. Persistent scarring has been noted in a number of instances, as in the present case. Recurrences were abnormally frequent, two cases of recurrence being noted in this small series. An eruption of scattered vesicles on the trunk and extremities was present in the authors' patient. As a rule mild leukocytosis is noted in the blood, the increase in the number of leukocytes being most marked in the percentage of polymorphonuclear leukocytes. The Wassermann reaction of the spinal fluid was reported to be normal in all the cases in which the fluid was examined. The present patient is the only one in the series in whom roentgenologic examination of the vertebrae revealed gross abnormalities. While herpes zoster usually presents a characteristic picture, confusion of the bilateral type with herpes simplex is apt to occur. This is especially true in cases of extensive eruptions of the latter. Other conditions that may cause difficulty in diagnosis include generalized herpes, varicella and dermatitis venenata.

### Degeneration of Spinal Cord in Pernicious Anemia.—

Hyland and Farquharson report the results of treatment in seventy-four persons with pernicious anemia associated with definite subacute combined degeneration of the spinal cord who were admitted consecutively to the public wards of the Toronto General Hospital between June 1926 and June 1933. Eight patients were moribund on admission to the hospital and died within a few days. The remaining sixty-six patients were treated with large amounts of liver preparations and prolonged rest. During a period of from four to twelve months in the hospital and subsequent observation in a follow-up clinic, forty-one showed marked and sixteen moderate improvement, while the condition remained stationary in nine. In no case was there real progression of the neurologic lesion. Improvement was maintained in all cases in which therapy was maintained as

directed. The most important factor in treatment is the administration of large amounts of liver preparation, the dose recommended being at least twice that required to bring about a prompt remission in a patient with anemia. Intramuscular therapy is the method of choice. The best results are obtained when the patient is kept at rest in bed during the early months of treatment. The level of hemoglobin is not a satisfactory index of the adequacy of liver therapy. Subacute combined degeneration may develop and progress while a patient takes sufficient liver to prevent the development of definite anemia. The relief of the various symptoms and signs of subacute combined degeneration is due to an improvement in function of the fiber tracts of the cord. The tendency to segmental distribution of the impairment indicates an origin in the spinal cord. Under adequate liver therapy a definite change in the pathologic picture occurs. All signs of active degeneration disappear, leaving an apparently healed lesion. Associated with this change there is great symptomatic improvement in the majority of cases. By administration of liver therapy in adequate amount, subacute combined degeneration can be prevented, its progression completely arrested and great improvement obtained, especially in cases of short duration. It is important that treatment be continued for prolonged periods before concluding that no improvement will occur.

**Endometrial Hyperplasia.**—Blair believes that the subject of endometrial hyperplasia is so interlocked with fibromyomas that any discussion of the former from a clinical standpoint without including the latter is incomplete. There were eighty-three hysterectomies for fibromyomas in the Vancouver General Hospital in 1934. Of these, sixty-seven showed definite hyperplasia of the endometrium. Such a uniform finding of hyperplasia among fibroid uteri is no coincidence. Indeed, there seems to be a close relationship between these two groups of cases. Each is a group of bleeding uteri in nearly every case; each has the same sort of bleeding surface in the majority of cases—a hyperplastic endometrium; each appears at about the same time in life, and each is treated in the same radical way. In other words, are fibromyomas of the uterus as well as endometrial hyperplasia caused by hypersecretion of estrogen? Fibroids seem to appear with the tide of civilization, and with them march hand in hand the spread of pelvic infection. When the surface of the ovary becomes so affected that the follicle cannot rupture, there is a gradual increase in estrogen in the circulation with no progestin to act as a buffer. Then appears the primary overstimulation of the endometrium, endometrial hyperplasia, and the ultimate overstimulation of the myometrium, with gradual fibroid formation. Fibromyomas are seen only in the human race; even the higher apes are said to be relatively immune. Also a number of the organisms which attack mucous membranes, particularly the gonococcus,

The defendant's relations with her father, said the Supreme Court, were such that she was not liable for the plaintiff's services unless she became so by reason of what she said or did. The rule is well established that a person who merely calls a physician to render services to another is not liable therefor in the absence of an express agreement, unless the person is legally bound to furnish such services. The defendant in this case did, according to the evidence, promise to pay for the services and ordinarily, said the court, this promise might make an entirely different case for the plaintiff. It showed not only that the defendant requested the services but also that she made a direct promise to pay for them. Such a promise is not collateral or secondary, but primary and original. It is not a promise to pay the debt of another but is a promise to pay the debt of the promisor and does not have to be in writing to be valid. But, said the court, when the defendant made the promise, the plaintiff was at liberty to accept or reject it. He could, if he chose, treat the injured man on his own credit. He could not, however, hold both the injured man and the defendant liable for his fees. If he gave credit to the injured man, he could not collect from the defendant, even though she had tendered an engagement direct in form. The defendant's sole obligation could not be treated by the plaintiff as a joint obligation without her concurrence. If the plaintiff gave any credit to the injured man, he elected to accept the defendant's engagement as collateral to that of the injured man. The plaintiff did, the court pointed out, make his original charges against the injured man and it must be assumed that he did so because he considered the injured man responsible for his fees. Having given credit to the injured man, the plaintiff may not, the court concluded, collect from the defendant. The judgment of the trial court was therefore affirmed.—*Lawrence v. Anderson (Vt.)*, 184 A. 689.

**Compensation of Physicians: Liability for Fees of Expert Witness.**—The plaintiff, a physician, sued to recover for the value of services rendered in giving expert testimony at the trial of an action brought by the defendant for personal injuries. The trial court held that the evidence did not support the plaintiff's claim and withdrew the case from the jury. The supreme court of New Jersey, on appeal, held that an attorney has implied authority to obligate his client to pay the fee of an expert witness called by him, and reversed the judgment of the trial court withdrawing the case from the jury. (*Klein v. Boylan*, 115 N. J. Law, 295, 179 A. 638; abstr. THE JOURNAL, Feb. 29, 1936, p. 735.)

The case was tried a second time, again resulting in a judgment for the defendant. The plaintiff appealed to the supreme court of New Jersey, apparently contending that the trial court erred in charging the jury that, if the plaintiff was employed by the defendant's attorney acting in his own behalf and for his own benefit, the verdict should be for the defendant. There was no evidence, said the supreme court, justifying the trial court in thus charging the jury. The evidence was clear that the plaintiff looked to the defendant for payment, and there was no intimation that the attorney obligated himself personally with respect to the fees of the expert witness. It was therefore prejudicial error to submit this issue to the jury. The judgment of the trial court was consequently reversed.—*Klein v. Boylan (N. J.)*, 184 A. 736.

**Autopsies: Liability for Unauthorized Autopsy.**—The wrongful dissection of a dead body, said the Supreme Court of Oklahoma, is regarded as a wilful and intentional wrong against the person entitled to the possession and control of the body for burial, and a recovery may be had for the mental anguish resulting from such a mutilation. The decided cases generally treat the unauthorized dissection as an interference with a legal right. This legal right is the right to have immediate possession of the body in its condition at the time of death, and control for burial. A petition, therefore, which alleges the right to a body, a refusal to deliver up the body on demand, and the performance of an unauthorized and wrongful autopsy thereon while it is withheld, states a cause of action for damages for the interference with legal rights, and mental anguish is a proper element of such damages.—*McPosey v. Sisters of the Sorrowful Mother et al. (Okla.)*, 57 P. (2d) 617.

*Ninth Annual Meeting, Held in Chicago, Nov. 6 and 7, 1936*

The President, DR. FRED M. SMITH, Iowa City, in the Chair

#### Duodenal Ulcer: Roentgenologic Demonstration of the Crater

DRS. FREDERIC E. TEMPLETON and THEODORE E. HEINZ, Chicago: This report has to do with about 350 cases of duodenal ulcer studied with especial reference to the roentgenologic demonstration of the crater and its clinical importance. In three fourths of the cases with clinical evidence of activity a definite crater was seen. In no instance was a crater found in a patient who gave an old ulcer story and who had no clinical evidence of activity at the time of the roentgenologic examination. The difficulty involved in the differentiation of true craters and "pseudocraters" is discussed. The clinical value of the roentgenologic demonstration of the crater as regards diagnosis, prognosis and therapy is emphasized.

#### Influence of Certain Drugs in Relation to Biliary Pain—Variations in Intrabiliary Pressure

DRS. WALTMAN WALTERS, JOHN M. MCGOWAN and WINFIELD L. BUTSCH, Rochester, Minn: Changes in pressure in the common bile duct have been studied in a group of cases in which operation had been performed for lesions of the biliary tract and in which, as a part of the operation, the common bile duct had been opened and explored, and the incision in it closed around a T tube. By studying changes in pressure in the common bile duct and correlating the various phases of pressure with roentgenograms, we have been able to demonstrate that attacks of biliary colic are associated with increase of pressure in the common bile duct from 0 or 20 mm. of water up to 200 and even 300 mm. of water; the increase results from spasm of the sphincter of Oddi preventing the bile entering freely into the duodenum. When a substance opaque to x-rays is employed, fluoroscopic and roentgenographic examinations reveal the spasm of the lower portion of the common bile duct or the sphincter of Oddi, with abnormal filling and distention of the intrahepatic ducts, during the height of the pain. Inhalation of amyl nitrite or sublingual administration of  $\frac{1}{100}$  grain (0.00065 Gm.) of glyceryl trinitrate reduces intrabiliary pressure and relieves biliary colic, and roentgenograms give evidence of release of the spasm of the lower end of the duct and of the sphincter of Oddi. Patients who experience pain following administration of morphine belong to the group of those who suffer from the so-called postcholecystectomy syndrome.

In more than twenty cases studied twelve days after removal of the gallbladder and exploration and drainage by T tube of the common duct, morphine one-sixth grain (0.01 Gm.) given subcutaneously has produced increase in pressure in the common bile duct, from 0 or 20 mm. of water up to 200 and even 300 mm. of water. Pressure begins from two to five minutes after injection of morphine and rises at a variable speed. In some cases rises in pressure are accompanied by typical attacks of biliary colic and frequently by nausea. Severe pain is com-

permitting transient bacteremias from the bacterial reservoirs of the body. Administration of specific immune serum, the phenomenon of bacterial dissociation and errors in technic of culturing played a definite but minor part in these differences. Postmortem autolysis of the tissues tends to destroy the more sensitive pathogenic bacteria, provided the time interval between death and postmortem examination is more than twelve hours.

### Granulocytopenic Fractions of Yellow Bone Marrow.

—Zichis isolated fractions that appear to have granulocytopenic properties by saponifying yellow bone marrow with alcoholic potassium hydroxide at room temperature. The active fractions were isolated by separation with distilled water and by petroleum benzine extraction. The former method affords a comparatively simple means of separation. However, by the latter method it is possible to obtain the fraction in a more concentrated form. In addition, the preparation isolated by the first method is active when administered orally, and the other preparation is active when administered intramuscularly to rabbits in which a condition of granulocytopenia was produced experimentally. Although a very highly active concentrate was prepared, it will be necessary to conduct further studies on the purification and concentration before any suggestion of chemical composition can be made. A modification of the method employed by Dennis was used to produce granulocytopenic conditions in rabbits and rats. This proved to be satisfactory. Although the condition obtained by this procedure may not be identical with that in human beings, it affords a convenient laboratory method of demonstrating the granulocytopenic activity of concentrates of yellow bone marrow.

### Surgical Treatment of Injuries to Peripheral Nerves.—

Adson asserts that the surgical treatment of injuries of the peripheral nerves is governed by the physiopathologic phenomena of degeneration and regeneration of these nerves. The character of the injury, whether it is contusion of a nerve, compression of a nerve by a blood clot or callus, a clean cut section or extensive laceration resulting in loss of nerve tissue or in avulsion of a nerve, more or less determines the type of

surgical operation that is indicated. The degree of paralysis and the interval between the time of the injury and the repair are important factors in selecting the operative procedures and in determining the indications for operation. The ideal operative measures are neurolysis of nerves which are partially paralyzed as a result of constriction and end-to-end suture following removal of the neuromas. Suturing should be performed in the first six months following the injury; interrupted silk sutures should be placed in the epineurium, without tension. Prevention of undue traction on the suture line and gentle massage of the paralyzed muscles during the period of recovery are essential to successful regeneration.

**Treatment of Delirium Tremens.**—Sperber points out that the sodium salt of *n*-methyl-cyclohexenylmethyl malonylurea immediately after intravenous injection in ordinary therapeutic doses aborted the attack in three typical cases of delirium tremens. The patients fell asleep for a period of from two to four hours, at the end of which they awoke for a brief interval and then returned to a deep sleep, the latter being the usual reaction following the natural ending of an attack of delirium tremens. On awaking, all were fully oriented and had no recollection of the attack. At no time was there a recurrence of symptoms. The observations suggest that the drug may be a specific remedy for delirium tremens, and this small series of cases is reported in the hope that its true value will be determined by others. Its possible value as a preventive in the predelinium state and as an abortifacient in acute alcoholic psychosis is suggested.

### The Function of the Small Intestine

DRS. LORIN D. WHITTAKER and J. ARNOLD BARGEN, Rochester, Minn.: This report is a part of an investigation of the function of the small intestine of human beings who have had stomas made in the terminal portion of the ileum, with or without an associated colectomy. Patients were studied as late as five and a half years after ileostomy. Repeated quantitative determinations of chemical constituents of the blood were carried out. There was consistently seen a moderate decrease in the values only for calcium in the serum following ileostomy. The values returned to normal at the end of one month and remained normal. The effect of ileostomy on the caliber of the terminal portion of the ileum was studied roentgenologically, at reoperation and at necropsy. A definite dilatation of the terminal portion of the ileum was found. There was no evidence, however, that the amount of dilatation present was sufficient to compensate volumetrically for the excluded colonic reservoir. The motor activity was studied by means of intestinal tracings to determine what part intestinal motility might play in the reduction in activity of the ileac stoma and in the thickening of the discharge that occurs following ileostomy. There was no fundamental change from normal in motor activity through the prolonged postoperative period of observation. The changes in activity of the ileac stoma and in consistency of the discharge cannot be ascribed to changes in motor activity.

### Alterations in the Respiratory Tract from Aspirated Vomitus

DRS. CARL W. APFELBACH and OSCAR O. CHRISTIANSON, Chicago: In moribund individuals, in the presence of dilatation of the gastro-intestinal tract and under the influence of general anesthesia, flooding of the respiratory tract with vomitus leads to acute alterations that have not been described and recognized anatomically and clinically to a degree proportionate to the frequency of occurrence. Hemolysis, hemorrhage, edema, acute emphysema and necrosis are the characteristic changes. Abscess and gangrene from aspirated foreign material are excluded from the discussion. Clinically acute dilatation of the heart, pulmonary embolism, coronary thrombosis and acute pulmonary edema are the usual interpretations. The characteristic alterations have been reproduced in dogs by injecting material from dilated stomachs into the trachea. The frequency of this complication has been reduced at the Presbyterian Hospital by an increase in aspiration of the stomach when dilatation is diagnosed. Even though it usually occurs in moribund conditions, it occasionally is the major complication causing death.

#### DISCUSSION

DR. M. W. BINGER, Rochester, Minn.: In 1926 and 1927 Dr. Wilder and I made a study of postoperative pneumonia in a series of 300 cases. We thought these were practically all aspiration pneumonias. Cultures were made from the sputum and practically all were hemolytic streptococci. There were some cases in which food was present in the trachea, probably because of regurgitation from the stomach and aspiration in the lung. I think this is important in surgical complications.

DR. CARL W. APFELBACH, Chicago: This condition may occur during labor, but during the last eight years we did not observe aspiration of vomitus in labor. I should have mentioned that Dr. Balfour emphasized the importance of pulmonary aspiration of vomitus as a complication of gastro-enterostomy and other operations on the stomach. It is a well recognized condition pathologically but has appeared in textbooks on pathology only occasionally, and the clinical textbooks do not give it importance that is proportional to its frequency.

### Comparative Effects of Protamine, Crystalline and Regular Insulin on Blood Sugar

DRS. GORDON B. MYERS and FRANK S. PERKIN, Detroit: The comparative effects of uniform doses of protamine insulin, crystalline insulin and regular insulin at 7:40 a. m. and 6 p. m. on the blood sugar before breakfast and three hours after each meal were studied in a group of ten diabetic patients. From the parallelism in the curves on regular and crystalline insulin, it would appear that there is little if any difference in their action when used in the manner prescribed. The duration of the hypoglycemic effect of protamine insulin was considerably greater than that of crystalline or regular insulin.

The comparative effects of single doses of protamine zinc, protamine calcium and plain protamine insulin at 7 a. m. daily were studied in ten patients with severe diabetes. The results with protamine zinc insulin were much superior to those with any of the other preparations. The average fasting level of 0.069 per cent would indicate that its hypoglycemic effect exceeds twenty-four hours. The group was better controlled on a single dose of protamine zinc insulin averaging 44 units than on an average of 3.3 doses of regular insulin daily totaling 60 units. Severe reactions have occurred between midnight and 5 a. m., from seventeen to twenty-two hours after the administration of protamine zinc insulin. They can usually be prevented by a small bedtime feeding.

Protamine zinc insulin was used successfully as a supplement to regular insulin in the treatment of diabetic coma. One patient who had required twenty doses of regular insulin totaling 300 units in her first attack of diabetic coma was brought out of a second attack of similar depth by a single dose of 100 units of protamine zinc insulin supplemented by two doses of regular insulin amounting to 70 units.

### Insulin with Prolonged Action

DRS. RANDALL G. SPRAGUE and EDWARD H. RYNEARSON, Rochester, Minn.: Comparative studies of the duration of the hypoglycemic effect of various preparations of insulin were made on young patients having severe diabetes of long standing. The observations show that the precipitation of insulin with protamines, as performed by Hagedorn, results in marked slowing and prolongation of its action. The addition of soluble zinc salts in small amounts to protamine insulin apparently causes a further slowing of its action, while calcium has the opposite effect. Crystalline insulin containing small amounts of zinc (insulin-zinc) as prepared by Sahyun, acts for only a slightly longer period than regular insulin. The gradual production of hypoglycemia by slowly acting insulin is attended by milder early symptoms than are observed in the hypoglycemia produced by regular insulin, although the late symptoms may be equally severe. The clinical management of severe diabetes is improved and simplified by the use of protamine insulin supplemented by small doses of regular insulin.

#### DISCUSSION ON INSULIN

DR. HENRY T. RICKETTS, Chicago: It is interesting in connection with the discussion of zinc that Rabinowitch has shown quite clearly that the addition of zinc to regular insulin in large amounts may so delay the action of insulin as to inhibit it completely for from six to nine hours; so there seems to be no question that zinc is the factor largely responsible for the delayed action of zinc protamine and insulin zinc. As to the toxicity of zinc, Rabinowitch has been able to produce no evidence of this from available data. I should like to ask Dr. Myers and Dr. Sprague if they have observed any patients on protamine insulin during acute infections. We have had three patients at Billings with mild infections of the upper respiratory tract on protamine in whom it was necessary to increase the amount of insulin. This seems to be quite out of line with former experience with regular insulin.

DR. MOSES BARRON, Minneapolis: This work with protamine insulin will probably prove to be almost as great an advance in the treatment of diabetes as the introduction of insulin in the first place was over the preinsulin treatment. The second paper showed how zinc insulin seems to have a more prolonged as well as more intense action than the plain protamine insulin. I recently had a patient in whom that was brought out. This patient had severe diabetes with an infection of the upper respiratory tract and a large abscess in the lung. The patient had to be given massive doses, from 70 to 100 units of protamine insulin daily. She also had to be given some plain insulin in the morning in order to eliminate glycosuria in the latter part of the forenoon. When given zinc insulin she seemed to be under good control. When this was changed to the plain protamine insulin she would at once develop a severe glycosuria, and later when she would be put back again on the zinc insulin she would often develop severe hypoglycemic reactions about 2 or 3 o'clock in the morning with severe convulsive seizures. Just one more point about the treatment of acidosis in diabetic coma: I believe that at no time should protamine insulin be given alone, since the action would be too slow and the patient's life would then be endangered.

**Undulant Fever and the Public Health.**—Green believes that prevention and control measures of undulant fever depend primarily on the ability of the practicing physician to recognize the disease, as 90 per cent of these cases are diagnosed as malaria, typhoid and paratyphoid. The author has had numerous interviews with persons who have suffered undulating febrile attacks, muscular rheumatism, arthritis and orchitis for months before receiving a proper diagnosis through a laboratory blood test. Secondly it depends on health officials and veterinarians, who should be charged with the responsibility of blood testing all cows and goats supplying milk for human consumption and the elimination of all reactor animals through segregation or destruction, preferably destruction. In areas in which the disease is prevalent or known to exist, the blood test should have precedence over the test for tuberculosis. Until the source of the infection is determined, all milk should be boiled or pasteurized. Human beings having the disease should be treated on the same principles as laid down for typhoid. General sanitary measures should be enforced. Suppression of flies and mosquitoes, allaying of dust and promotion of cleanliness should not be neglected.

**The Nodal Triangle.**—Nolan points out that the nodal triangle, an abnormal finding observed in lymphatic influenza, or so-called glandular fever, is easily elicited by gentle, digital palpation, the palpating fingers running along the vessel's course on the surface. The condition when elicited is definite. Sacculated nodes ranging from the size of a pea to that of a bean are in linear arrangement converging at the inner aspect of the knee joint but never below this point. These lymphatic dilatations or sacculations take on temporarily the nature of a lymphangioma or fibroma. They lie in the subcutaneous tissue just below the corium; the skin is normal in appearance and shows no local signs of inflammation over nodal triangular

lines. By palpating over these sacculations with pressure, pain is elicited along the nodal chain. The sign is considered of extreme importance for purposes of early differentiation, as a possible explanation for muscular asthenia, and as another check in establishing the fact that the organism or virus causing influenza in some juvenile epidemics has a specific action on the lymphatic system of the body, thereby producing a train of signs and symptoms. When the patient shows by the blood count and other studies an atypical picture of so-called glandular fever and the cervical, axillary and inguinal adenopathy is apparently normal, this sign in the lower extremities will furnish the evidence demonstrating adenomatosis in an anatomic location rarely if ever looked for. Its presence is apparently due to a mechanical irritation (muscle squeeze) during the prodromal or acute introductory stage of the influenza virus affecting the lymphatic system.

**Pulmonary Cysts.**—Oughterson and Taffel believe that cysts which are filled with fluid and are indistinguishable from intrathoracic neoplasms should be explored and, if possible, removed. Infected cysts which present the same symptoms as those of chronic lung abscess or infected bronchiectasis are subject to the same principles of treatment as those of the so-called chronic nonspecific pulmonary suppuration. The treatment of large infected peripheral cysts is similar to that of chronic encapsulated empyemas with communicating bronchopleural fistulas. Adequate drainage must be instituted. After the infection subsides, cauterization of the bronchial orifices with closure of the wound by muscle pedicle grafts may be carried out. If the cysts are too large to be obliterated in this way, the lobe containing them may be resected. It is believed that pulmonary cysts, like those of the other parenchymatous organs of the body, do not all arise as a result of a single common mechanism but are congenital, inflammatory, mechanical or neoplastic in origin. The clinical manifestations are protean, and the correct diagnosis is frequently made only at operation or at necropsy. The authors used a new therapeutic procedure in their patient suffering from a tension pneumothorax with multiple, large air cysts in the right middle and lower lobes. The bronchial openings communicating with the cysts were made so large and numerous that air could not be withdrawn rapidly enough through a needle. An open thoracotomy was performed, at which time the walls between the cysts were divided and a shrunken upper lobe was disclosed. High negative pressure served to collapse the cysts completely and to expand the upper lobe until it filled the hemithorax. This negative pressure was maintained until the lung became adherent. Physical examination, as well as roentgenograms, revealed normal lung fields two years after the operation. There has been no recurrence of symptoms.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (\*) are abstracted below.

**Blood Volume Changes in Eclampsia.**—Through the study of the constituents in the blood and urine of toxemic patients Dieckmann found that a concentration of the blood, which may be relative (below the average for the period of pregnancy) or absolute (less than the normal for the nonpregnant patient), occurs in eclampsia. This concentration can be demonstrated by blood and plasma volume determinations, but it is best demonstrated by serial determinations of hemoglobin, cell volume or serum protein concentration. The change in concentration of these substances is not always parallel, but the direction of change is usually the same. A concentration of the blood and plasma is not the cause of the eclampsia, but it is intimately associated with the convulsions, coma, oliguria and the various cerebral, visual and gastro-intestinal symptoms. A blood dilution is associated with clinical improvement as determined by a diuresis, cessation of the convulsion, return to consciousness and decrease in temperature and pulse. Death occurred in three patients in whom a permanent blood dilution could not be maintained. Since the exact cause of eclampsia is unknown and a concentration of the blood occurs which may be so marked as to be incompatible with life, treatment that will dilute the blood should be instituted. If the case is mild, almost any type of treatment is efficacious. If the case is severe, treatment that comprises control of the convulsion, dilution of the blood and relatively early delivery must be instituted.

**Fatal Air Embolism on Eighth Day of Puerperium.**—In their case of fatal air embolism, which occurred on the eighth day post partum, Quigley and Gáspár found that the cause of death was due to air embolism by way of opened uterine sinuses and retained small pieces of decidual tissue with hemorrhage.

There evidently had been some bleeding from the placental site due to the retained small particles of decidual tissue. Blood clots were formed not only around the retained small pieces of decidual tissue but also in numerous uterine veins just beneath this area. As the patient went into the knee-chest posture, the lower pole of this blood clot became separated from the uterine wall and several large veins became opened. At first hemorrhage occurred, suddenly followed by the suction of air into these gaping veins in sufficient quantity to block the pulmonary artery and the right side of the heart.

**Gonadal Disturbances in Behavior Problems.**—Molitch and Poliakoff observed eighty-one boys with gonadal disturbances from the standpoint of diagnosis, mental level, school achievement, behavior, personality and treatment. Except for those with delayed secondary sexual development, gonadal disturbances are not of frequent occurrence in boys with behavior problems. Boys with deficient gonadal function tend to be brighter than the control group. The children with hypergonadism are below the average of the control group. The school attendance and achievement were not much different from that of the control group, but the boys with undescended testes were the most serious school behavior problems. The offenses causing commitment consisted essentially of truancy and stealing. This is equally true for the control group, but the boys with hypogonadism were particularly noted in the stealing category. Sexual offenses were quite rare, and occurred only in one boy with hypergonadism. The boys with gonadal dysfunctions were found to be unstable, immature and infantile. The children with undescended testes were the most unstable, but the entire group were less deviated than children with dyspituitarism. Within the institution the boys with gonadal disturbances were making a good school adjustment but were among the retarded from the standpoint of conduct and work. Eleven boys with undescended testes were treated with the gonadotropic factor from the urine of pregnancy, with excellent results in seven cases.

**Bilateral Herpes Zoster Complicating Tuberculosis.**—Epstein and Jacobson reviewed the literature and found reports of only forty-six instances of bilateral zoster. The articles

valve cusps in the hearts of five infants up to 6 months of age. The small dark red nodules projected on the atrial aspects of the cusps a short distance from their edges. They varied in size from 0.2 to 1 mm. in diameter, and the elevations produced were smooth with no external opening visible. The authors support the view of Haushalter and Thiry that blood cysts originate from the blood in the heart cavity that has been pressed into a valve cusp. In embryonic hearts the traction of the chordae tendineae tends to produce furrows or undulations in the delicately meshed fibrous structure which has not yet become differentiated into special layers in the cusp, and this is especially marked on the ventricular aspect. If fusion of the edges of these furrows occurs, there are formed localized blood cysts which become incorporated in the substance of the cusp. On serially sectioning the cusps, fusion of the edges of the furrows was seen to be taking place leading to the formation of tunnels of variable size. As the result of traction and pressure, these become enclosed spaces which may eventually appear as swellings on the atrial aspect of the cusp. Each cyst had a complete endothelial wall surrounding it, and those which presented on the atrial aspect of the cusps acquired an additional layer of atrial endothelium on their projecting surfaces. Blood cysts do not appear to have any pathologic significance and are a common anatomic observation in the valves of the new-born and infants in the first few months of life.

**Optic Atrophy in Pernicious Anemia.**—Cohen believes that the lesions caused by loss of function followed by degeneration of nerve elements and their resulting symptoms might precede by a considerable period the clinical manifestations of pernicious anemia, and at first the effects would appear to be temporary and amenable to treatment. But, if left untreated, the pathologic changes progress to irreparable and complete neuron degeneration. The two cases of optic atrophy presented show that clinical examination cannot determine the proportion of temporary to permanent changes responsible for the visual loss, for the resulting symptoms and signs of the two are identical. It is in this sense that the term "optic atrophy" is applied to the pathologic change responsible for the visual disturbances described, and the cases demonstrate that this type of optic atrophy can precede other neurologic and blood changes in pernicious anemia. The diagnosis of pernicious anemia can be determined by the age of the patient (middle age) at the onset of optic atrophy, the steady deterioration in visual acuity before treatment is commenced and the considerable improvement that immediately follows the adequate parenteral administration of liver extract. Of the many cases

of unexplained optic atrophy a few human beings can be spared the tragedy of progressive blindness if an unmasked pernicious anemia is recognized early as the cause of failing vision and adequate treatment given. The knowledge that failing vision due to optic atrophy might be the presenting symptom in pernicious anemia will doubtless facilitate its recognition at an early stage.

### Rhythmic Movements Within Red Blood Corpuscles.

Two years ago, while studying a fresh specimen of human blood by means of the supravital technic, Forkner and his co-workers observed that practically all red blood corpuscles exhibited peculiar movements within or on the surface of the cells. The phenomenon has been demonstrated repeatedly. The phenomenon is present in the red corpuscles of normal individuals and in patients suffering from a variety of diseases. It may be seen easily in fresh blood films made by allowing a coverslip, on the surface of which is a fresh drop of blood, to fall on a glass slide, the coverslip then being rimmed with petrolatum. The movements are best seen with an oil immersion lens and a 10× eyepiece in an area at which the cells are not too much compressed. They appear more clearly with binocular vision but are seen also with an ordinary monocular microscope of standard type. Rather intense illumination is necessary. Three types of movements of or within the cells may be observed: (1) a coarse jiggling of the corpuscles, (2) an irregular but more or less constant rate of pulsation of the borders of the corpuscles and (3) an intense, exceedingly rapid and apparently rhythmic activity within the cells themselves. The activity may represent a mechanism of molecular streaming whereby the molecules circulate within the cell at a rapid rate. If this is true, it is a solution for a problem which is of some importance in the physiologic activity of the erythrocyte. The mechanism of rapid oxidation and reduction of hemoglobin within erythrocytes may be intimately related to the very intense and rapid activity within the cells themselves. Such a mechanism would explain at once how erythrocytes are able to act so efficiently.

are active only in man. Infection is the only cause of endometrial hyperplasia or fibromyomas, but any entity that inhibits ovulation may cause it, and pelvic infection is a common one. Attention should be drawn more toward the ovary and less toward the uterus in a search for the cause of the trouble. Preliminary biopsy of the endometrium should have a greater place in the preoperative calculations than heretofore. Thorough endometrial biopsy (curettage) and the artificial menopause should have a greater place in the treatment of selected cases than is generally practiced. Supplementary endocrine therapy should continue to attract the profession in the hope that it may eventually prove satisfactory.

**Heparin and Vascular Occlusion.**—Murray and his associates studied the influence of heparin in the prevention of the occlusion of traumatized veins in dogs. The evidence indicates that no occlusion occurs while heparin is being injected intravenously and if its administration is continued for a sufficient length of time healing of the intima takes place and there is a greatly reduced tendency for the vessel to occlude when injection is discontinued. Heparin also effectively prevents the vascular occlusion that follows the administration of sodium ricinoleate. Heparin may be injected intra-arterially in an extremity at such a rate that the blood flowing through the limb is definitely affected, while much less effect on the blood as a whole is produced (regional heparinization). The remarks on the effects of heparin refer only to the results of general heparinization. To secure this general effect, heparin is injected intravenously and the blood throughout the body is rendered incoagulable to a degree that depends on the amount of heparin injected. The cruder preparations of heparin had definite toxic effects in dogs, while the more highly purified material (70 units per milligram) has produced remarkably little disturbance. A substance effective in the prevention of vascular occlusion in animals due to mechanical or chemical causes deserves a clinical trial, provided it can be shown that doses effective in delaying coagulation of the blood have no deleterious results. The effects of the administration of purified heparin to patients was studied in May 1935 and a detailed report of the clinical experience is to be presented.

**Intra-Ocular Lesions Associated with Pregnancy.**—Bovenmyer declares that in the toxic pregnant woman the slightest disturbance referable to the eyes, a mere dimness or inconsiderable blurring of vision, is a danger signal. Control of the eyegrounds of the toxic patient may give timely warning of a threatened catastrophe. Retinitis occurring in a pregnant woman may be connected with a chronic nephritis present before pregnancy, or it may be an expression of a toxemia of pregnancy that may or may not be giving rise to a concomitant pregnancy nephritis. The prognosis for life and health in the pregnant woman with retinitis will depend largely on whether or not there is a chronic nephritis. Because of the greater danger from a retinitis that has developed on the basis of a nephritis antedating pregnancy, it is important to find, if possible, some

indications in the eyegrounds to distinguish between the types of retinitis. The presence of sclerotic arteries denotes a previous nephritis with an accompanying hypertension, and their absence denotes, though less positively, that the retinitis is gestative. Radially disposed streaks of exudate, the star figure, are looked on as originating from a preexisting renal disease. The view accepted by the majority seems to be that the prospects of return of good vision are favorable, with certain exceptions or qualifications, such as that the chances are hardly favorable if there are changes in the macular region or if there is retinal detachment or papilloretinitis. Symptoms pointing to intra-ocular involvement and eyeground changes, showing that the toxins have attacked the retina and optic nerve, present to the physician the grave responsibility of deciding whether or not prompt emptying of the uterus is indicated to save the mother's life or to preserve her future health or vision. The preeclamptic woman and the woman with pernicious vomiting of pregnancy should have the eyegrounds controlled frequently with the ophthalmoscope. Ocular complications are of serious import in pernicious vomiting; Stander regards the appearance of hemorrhagic retinitis in pernicious vomiting as an absolute indication for immediate termination of the pregnancy. Instead of attacking the peripheral nervous system, as in retinitis, the toxins of pregnancy may attack the central nervous system in the visual center. Here belong those cases of eclampsia with and without convulsions, with amaurosis, in which there are no changes in the eyegrounds or at most a fleeting edema of the papilla. The visual disturbances may be caused by insult to the cortex. Toxic amaurosis, Bruce says, is one of the most valuable signs of an impending eclampsia. In cases of disease of the optic nerve in pregnancy, a hypophyseal origin of the disturbance should be suspected. Definite tumor symptoms need not be present; to save the sight, the continuing hyperplasia must be checked by emptying the uterus.

**Clinical and Postmortem Blood Cultures.**—Burn and Harvey obtained clinical and postmortem blood cultures from 212 individuals, 147 of which were positive and sixty-five were negative for bacterial growth. Agreement between both blood cultures occurred in 125 of the 212 cases and disagreed in eighty-seven. Contaminants were responsible for the discrepancies in twenty-two. The greatest discrepancy was due to the presence of negative cultures in seventy-three of the individuals. Sixty-five of these were in the clinical cultures and only eight at necropsy. The most important factor responsible for the negative clinical cultures in these studies was the time at which the last clinical culture was taken with relation to the death of the individual. Other influences were those controlling bacterial invasion into the blood stream, the development of mixed infections in the tissues and anatomic injuries to mucosal linings

evolution of tuberculosis in young children, in children who have had tuberculosis for a short time on development of measles and in children who are suffering from acute tuberculosis, regardless of age. As a rule, acute tuberculosis complicated by measles evolves toward disseminated miliary tuberculosis or tuberculous meningitis. Stimulation, reactivation and aggravation of tuberculosis in measles is due to dysergia and enanthemic changes of the respiratory tract in the course of measles. Reactivation and reagravation of tuberculosis take place within a period no longer than a year after measles. Any late change in the evolution of the former cannot be related to the latter. The reactivation of tuberculosis following measles can be prevented by administering serum from convalescents. The latter is especially indicated in all children with secondary allergy or sensitivity to tuberculosis as well as in children exposed to a reinfection and in those under the age of 5 years.

**Vaginal Trichomoniasis.**—Nicholson and Peralta Ramos state that *Trichomonas vaginalis* plays an important part in the etiology of persistent refractory vaginal discharge. Trichomoniasis is frequent. The authors found it in 31 per cent of the cases examined in a gynecologic clinic in which the patients suffered from persistent vaginal discharge. It is more frequent in colored than in white women, especially in those who do not follow hygienic habits. The infection may be acquired by contagion in public baths in stagnant water and by using personal belongings of patients suffering from the infection. The authors failed to find any case acquired through sexual relations. Trichomoniasis should be considered a nosologic entity, as it gives a definite pathologic picture, and the phenomena developed in the course of the infection are characteristic of the latter. For diagnostic purposes the authors used the fresh drop method, in which the drop is stained with a saturated solution of brilliant cresyl blue in a physiologic solution. In six groups of patients the authors used the following methods of treatment: (1) painting of the vagina with a 5 per cent solution of mercurochrome every other day and later on every third day, (2) embrocations of petrolatum with quinine sulfate every other day, (3) daily douches with a 1:1,000 solution of mercury bichloride followed by an application of a 5 per cent solution of boric acid every other day, (4) a daily alkaline douche and two tablets of chiniofon (taken deep in the vagina by the patient), (5) two or three pills daily of an arsenic derivative and (6) daily vaginal painting with a 1:1,000 solution of mercury bichloride followed by an application of a 5 per cent solution of boric acid. Complete cure was obtained in all cases in from thirty to ninety days. The most resistant types are cystic trichomonal infections. The treatments with mercury bichloride and the arsenical preparation gave the most rapid and satisfactory results with permanent cure of the infection.

**Treatment of Lamblia.**—Echemendia considers lamblia of importance, especially because of the digestive and general disturbances it causes. In many cases the digestive

disturbances are etiologically misinterpreted and an erroneous treatment is given. The clinical picture consists of intestinal dyspepsia associated with enteritis and mucomembranous enterocolitis or rectocolitis, which frequently are of a dysenteriform type. There are pneumatosis, colicky pains and sometimes infection of the biliary tract. Identifying the parasite in the feces, after administration of a cholagogic saline purgative, or in the mucus of the duodenal secretion obtained by catheterization during stimulation of the gallbladder, is of importance. Lamblia is a stubborn infection from a therapeutic point of view. The author reports satisfactory results from the administration of hydrochloric acid to adults and lactic acid to children, alternating with the parasiticide treatment. The latter consists in the administration of trivalent or pentavalent arsenicals for adults, chiniofon for children and an iodine-quinoline preparation in intolerant cases due to liver insufficiency. As a rule, four or five alternate acid and parasiticide treatments are required to control the infection. Discontinuation of the treatments is determined by negative results of coprologic examinations obtained on three consecutive examinations. The author is experimenting with some other parasiticides, the use of which is too recent to permit conclusions. According to the author, lamblia should be given especial attention in the zone of Chaparra, because many cases of gastroduodenal disturbances in children of that region originate in lamblia.

**Intussusception from Ascariasis and Trichocephalosis.**—Sala Penisello and his collaborators say that the ileocecal is the most frequent type of pathologic intussusception. Ileocecal intussusception is rare. The authors' patient, aged 2, showed a grave clinical picture, consisting of colic pain, colic disturbances and symptoms of acute appendicitis. Necropsy revealed peritonitis and ileocecal intussusception caused by ascariasis and trichocephalosis. The authors say that ascariasis alone or in association with trichocephalosis may produce colic disturbances and grave symptoms of acute appendicitis in children. It is necessary, therefore, to make fecal examinations as soon as the symptoms appear. In children suffering from intestinal parasitism it is found that 6.57 per cent is caused by ascarids, 52.74 per cent by Trichocephalus and 14.12 per cent by both parasites. In the authors' case the formation of eosinophils at the site of intussusception was verified by the study of histologic preparations. According to the authors, intussusception depends on a local factor which simultaneously stimulates peristalsis and antiperistalsis in two contiguous intestinal segments of different calibers. They believe that ileocecal intussusception in their case originated in associated alterations of antiperistalsis of the large intestine and peristalsis of the small intestine due to chronic inflammation of the enterocolic muscular layer.

**Actions of Raw Apple Pulp.**—About five years ago Bittner began using the apple treatment in all adults and children suffering from intestinal infections. In 946 patients less than 10 years of age in whom severe diarrhea was a symptom there was only one death under apple therapy. In this case meningeal symptoms were present at the time treatment was started. Previous conceptions regarding the action of apple pulp on the intestinal tract must be revised entirely. The accepted theory that bulk and roughage are irritating to the intestine and stimulate peristalsis must be excepted in the case of apples, as the action of this bulk on the intestinal tract is soothing and decidedly constipating even to the highly inflamed and irritated intestine of young infants suffering from severe dysentery. There are definite rules that must be followed if the best results are to be obtained. The apples must be eaten on an empty stomach, they must be finely chewed, they must have sufficient time to leave the stomach before being mixed with other foods, foods of high protein content seriously minimize the effect of the apple and in seriously acute cases will absolutely neutralize the beneficial effects expected, and cooking temperature greatly impairs the therapeutic value of apples. It is the author's belief that the action of apple pulp is not one of a germicidal nature but that it is entirely one of absorption of the toxic effects of bacterial invasion. He believes that the only effect apple pulp has on the intestinal flora is that of removing exotoxic products of bacterial growth, thereby relieving the system from the absorption of these products and allowing the blood stream defenses to concentrate directly on the bacterial invasion. In other words, the action is similar to the drainage of an abscess.

Congenital Cysts. D. D. Paulus, Oklahoma City.—p. 447.

**Giant-Cell Tumors of Bone and Parathyroidism.**—Goodman believes that two factors must be concerned in the development of a giant-cell tumor. It is readily seen that, because hyperparathyroidism exists, a giant-cell tumor does not necessarily follow, and that an injury alone does not always produce a giant-cell tumor. However, an injury in addition to hyperparathyroidism will probably produce such a tumor. These two factors produce a giant-cell tumor because the bone is already rarefied and the injury causes a hemorrhage in that space. The hemorrhage organizes and forms granulation tissue. This tissue proliferates and so continues as "proud flesh" or as granulation tissue does on certain occasions on the surface. The granulation tissue presses on the walls and they expand, and, when bone is being destroyed, giant cells are always present. The giant cells are probably nothing but a group of the tumor cells grouped together, the better to digest the bone. The idea that giant-cell tumors are simply granulation tissue modified by confined hemorrhage is supported by the facts that (1) the two are similar in appearance microscopically and macroscopically, (2) both respond to cauterization, (3) irradiation will slow or completely inhibit the growth of either, (4) operative removal in either case will result in a cure and (5) both have a tendency to recur if treated indifferently.

\*Glutathione and Malignant Growth. C. Voegtlin, J. M. Johnson and J. W. Thompson.—p. 1689.

**Glutathione and Malignant Growth.**—Voegtlin and his associates found that it is possible by means of a diet deficient in cystine (and presumably methionine) to cause a marked slowing or even a cessation of the growth of a typical neoplasm (spontaneous mammary carcinoma). The same diet inhibits normal growth of young mice. Following a period of inhibited tumor growth, the administration of either cystine or glutathione causes a marked stimulation of tumor growth. A similar increase in the growth rate of young mice is produced by the cystine supplement. Dyer and du Vigneaud (1936) reported that the growth of normal rats on a cystine deficient diet is accelerated by the oral or subcutaneous administration of glutathione. It would seem, therefore, that with respect to the growth-stimulating response to cystine or to glutathione there is no essential difference between normal growth of young mice and rats and the growth of the spontaneous mammary carcinoma. It is believed that progressive neoplastic growth requires a sufficient supply of cystine (or cysteine) for the synthesis of tumor proteins. Since glutathione occurs not only in normal but also in malignant tissues, it would seem also that the growing tumor must be supplied with glutathione or its constituent amino acids, particularly cystine (or cysteine). Evidence is accumulating which indicates that the proliferation of this typical malignant tumor can be inhibited by diets deficient in certain essential amino acids or peptides. It remains to be seen whether other types of malignant tumors, especially those induced by carcinogenic substances, behave similarly.

sepsis with metastatic pyemic foci, while ten patients presented a picture of sepsis without localization. Of the latter group seven died and three recovered; of the former, one died and fifteen recovered. Necropsies of the eight fatal cases revealed that all belonged to the irreversible type of sepsis which does not recover under any form of treatment. The beneficial effect of small blood transfusions suggested that the effect was that of stimulation rather than of substitution of the blood volume. The author believes that the stimulating effect is related to the phenomenon of colloidoclasia. He therefore resorted to the use of incompatible blood because it makes the phenomenon of colloidoclasia more pronounced. The maximal dose was 30 cc., introduced once in five days. The maximal dose for heterogenous (goat) blood was 6 cc. The reaction, which took place from one and one-half to two minutes after infusion, was characterized by redness of the face followed by pallor and moderate cyanosis of the face and lips, sweating of the forehead, pains in the back and in the extremities and increased respiration, accompanied sometimes by coughing and occasionally by vomiting and by acceleration of the pulse (from 120 to 130 a minute). This reaction was followed from ten to fifteen minutes later by a chill and a rise of temperature. The reaction reached its height in from one to one and a half hours and gradually subsided in about six hours. Four of the fatal cases failed to react. The author demonstrated that hemolysis begins as early as five minutes after the transfusion and lasts for from twenty to twenty-five minutes. The mortality rate of 30 per cent is quite low for this type of sepsis. Transfusions of compatible blood were practiced in the course of the treatment in order to check the developing anemia.

**Irregularities of Pulse in Pulmonary Tumors.**—Among thirty-six patients with pulmonary tumors, Kamerling and van Nieuwenhuizen found eight with irregularities of the pulse. Auricular fibrillation was observed in six, paroxysmal sinus tachycardia in one and paroxysmal ventricular tachycardia in another. Since these irregularities sometimes occur as the first symptom of bronchial carcinoma, they are of a diagnostic and prognostic importance. In accordance with the observations of other investigators on the origin of paroxysmal tachycardia in animal experiments and in man, the authors regard vasal and sympathetic irritation as the cause of the symptom in patients with pulmonary tumors. Distinct signs of sympathetic stimulation (exophthalmos and dilated pupils) were found in some cases and necropsy disclosed a damaged vagus nerve in a few instances. These observations afford clinical confirmation of the extracardiac genesis of a number of arrhythmias found experimentally.

**Plasma Proteins in Nephrosis.**—Ehrström shows that, if an aqueous solution of congo red is shaken with carbon and centrifuged or filtered, total discoloration takes place; but if a plasma is colored with congo red in vivo or in vitro, it cannot be discolored in the aforementioned manner. To be sure, there is some discoloration and the various plasmas behave in different ways. Plasma from persons with normal kidneys, which is free from protein changes and which has been colored in vivo, loses 20 per cent of the coloring matter, and, if colored in vitro, loses 8 per cent of its coloring matter. In contradistinction to this, the plasma of patients with various nephropathies

and more or less severe albuminuria loses 37 and 57 per cent, respectively, of the coloring matter. If the globulin fraction is withdrawn from the plasma, the discoloration tendency still differs and is even more pronounced than in the whole plasma, the discoloration amounting to from 40 to 55 per cent in persons with normal kidneys and to from 60 to 100 per cent in patients with nephropathies. The degree of discoloration is not dependent on the quantitative ratio of the plasma proteins, the withdrawal of the globulin, the albumin: globulin quotient, the cholesterol content, the rest nitrogen, the morphologic composition of the blood, the sedimentation reaction or the tendency to edema. The coloring matter that is excreted in the urine after intravenous administration is bound to the urinary protein. The discoloration of the plasma is not proportionate to the degree of albuminuria. The increased discoloration (reduced absorption capacity) of the plasma of patients with severe albuminuria explains why the intravenous congo red test (according to the method of Bennhold) is positive in these cases in spite of the slight elimination of the coloring matter in the urine. In some cases the discoloration of the plasma in vitro may be increased in spite of the fact that the intravenous congo red test gives normal values.

**Influence of Body Posture on Heart Minute Volume.**—In a number of postural experiments, Nielsen watched the behavior of the circulation. He found that in healthy persons the minute volume of the heart is approximately 10 per cent larger in the recumbent than in the sitting position. The corresponding beat volume was 20 per cent larger. In tests on three patients with heart disease, the minute volumes were on the average 20 per cent larger in the recumbent than in the sitting position. On the basis of these results the author considers it probable that the aforementioned changes in the cardiac minute volume during postural changes may play a part in the development of orthopnea and of cardiac asthma.

**Uremia Due to Dehydration.**—Meyler demonstrates that an extrarenal uremia may develop as the result of dehydration. This form of uremia arises because dehydration leads to toxic protein destruction. The nitrogenous end products cannot be excreted sufficiently because there is a more or less marked oliguria and because the renal function is impaired under the influence of the lack of fluid and of the hypotension. The author describes several cases of uremia due to dehydration which could be cured by abundant supply of fluid. Under the influence of this large fluid intake the toxic protein destruction disappears, the diuresis increases and the renal function improves. The improvement of the renal function manifests itself by an increase in the maximal concentration. When the sodium chloride content of the blood had increased the author generally used a 5 per cent dextrose solution for subcutaneous administration. When the sodium chloride is at a normal level or slightly increased, it is better to use physiologic solution of sodium chloride. If dextrose solution is given in these cases the dilution of the blood may cause a fall in the sodium chloride content, which may have a harmful effect. A case is described of a male subject who was extremely dehydrated as the result of diabetic polyuria. This case shows great resemblance to the experiments of the Mackays, who made rabbits uremic by producing extreme dehydration with injections of dextrose solution. In gastric hemorrhage this form of uremia will develop because loss of blood means loss of fluid, and sometimes, in a severe gastric hemorrhage, no supply of fluid is allowed for days. Moreover, it is emphasized that in uremia due to lack of salt there is always a marked dehydration, which plays an important part in producing uremia. Lack of salt leads to protein destruction. Dehydration has the same effect; moreover, it causes oliguria. These factors together lead to uremia.

#### CORRECTION

**Riboflavin Instead of Acriflavine.**—In the abstract of the article by Verzá and Laszt (*Nature* 138:844 [Nov. 14] 1936) in THE JOURNAL, January 23, page 338, "acriflavine hydrochloride" should read "riboflavin" (or "lactoflavine"), and "acriflavine phosphoric acid" should read "riboflavin phosphoric acid." This error arose through the use by the authors of the term "flavin," which word, spelled with a final e, has long been represented in medical literature as a synonym for the antiseptic acriflavine.

This Mysterious *pu*. W. N. Kemp.—p. 23.

**Sequels of Anesthesia.**—This series includes 2,520 administrations of inhalation anesthetics, personally given or supervised by Kaye in the period from February 1931 to December 1935. Rather more than half of the administrations were performed in hospital practice and the rest in private practice. There were no fatalities on the operating table. One fatal case of pulmonary congestion following entry of vomitus into the lungs was directly attributed to the anesthetic. Two cases of fatal respiratory sequels might perhaps have been averted by a different anesthetic technic. No other postoperative deaths were attributed to the anesthetic. In Australia the "standard" anesthetic is ether, and the gaseous anesthetics are reserved mainly for the less good "anesthetic risks." The choice of anesthetic seldom erred in respect to safety at the time of operation, but it occasionally did so with respect to subsequent respiratory sequels. The incidence of postanesthetic vomiting was investigated in 1,295 cases. The lesser vomiting after gaseous anesthetics as compared with ether was very apparent. The superiority of gaseous anesthetics was manifested in the "no vomiting" and "slight vomiting" classes, and the ratio of moderately severe or severe vomiting was much the same whether gas or ether was employed. Figures indicate the great superiority of gaseous anesthetics over ether in each type of operation, so far as the milder degrees of vomiting were concerned. The more severe grades had much the same incidence, independent of the anesthetic used, a fact which may suggest that certain individuals, for biochemical or physical reasons, are prone to severe vomiting regardless of the anesthetic used. There were fifteen cases of respiratory sequels (bronchitis and pneumonia): three due to a faulty choice of anesthetic, four to technical errors and seven to various causes. The number of cases of postoperative psychosis in the present series was not recorded but was probably five or six. The onset usually occurred several days after operation and bore no apparent relationship to the anesthetic technic. The author has an impression that permanent psychotic changes are encountered rather frequently after the operation of prostatectomy. One patient in the series suffered from corneal abrasion. He had struggled during the induction stage and either received a splash of ether in the eye or, more probably, was injured by the gauze face cover.

**Pathogenesis of Hysterical Skin Disorders.**—Haxthausen submitted eight patients with pathomimia to experimental exposure of their skin to mechanical rubbing, Rumpel-Leede's test, ultraviolet irradiation, freezing with carbon dioxide snow and the pricking into the skin of a drop of 1 per cent solution of morphine and 30 per cent solution of silver nitrate. The reactions induced thereby were compared with those following similar experiments conducted on healthy controls. The eight cases of pathomimia presented lesions of varying types, mainly excoriations and ulcerations. Common to them all, however, was their typical artificial stamp. In no single instance, with any one of the tests employed, did there occur a reaction to be distinguished qualitatively from corresponding responses in normal persons. Nor was it possible in any case to demonstrate abnormally severe or particularly persistent reactions. In

patients with pathomimia the skin reacted in every way exactly as a normal skin toward the irritants used. Therefore, no ground can be deduced for the supposition of a particularly increased responsive capacity on the part of the skin of patients with pathomimia. With regard to the question of the pathogenesis of these cutaneous disturbances, it would seem reasonable to cast the deciding vote in favor of the psychic changes and to interpret the pathomimic lesions as being determined by influences of a morbid nature acting on a skin reacting alone in a normal manner toward the actual irritative effect. The intensity, however, with which the traumatization is conducted may be dependent on the hypalgesia or analgesia observed so frequently in these patients.

**Doses of Intra-Uterine Radon Tubes.**—Oddie shows that in different methods of treatment of carcinoma of the cervix uteri the ureters may be in danger, to varying extents, of receiving a dose appreciably greater than the minimal dose applied to the area treated. A satisfactory procedure is to have the dose at the ureters only from 75 to 80 per cent of the minimal dose in the region. This is obtainable by a critical choice of the strength and geometric distribution of the various component active lengths employed in the treatment. The adjustments required to effect this reduction in the dose on the ureters necessitate a general reduction of the doses received at most of the points inside the region treated, but the minimal dose in the region may still be maintained at an adequate value to destroy the malignant cells. Since all the other points inside the region receive, in any case, doses considerably in excess of the minimum, this reduction should not result in any loss of efficiency in the treatment. The method is suitable for use with radon, as containers are constructed to the required lengths and linear strengths. However, if radium is used the choice of suitable strength and size is limited. The radiation field from an arrangement of radon tubes can be altered to provide dosages adequate for treatment in the growth and still protect adjacent normal tissue from excessive irradiation.

\*Blood Cysts in Human Cardiac Valves. D. R. Dow and W. F. Harper.—p. 117.

**Blood Cysts in Cardiac Valves.**—During their investigation of the vascularity of seven human cardiac valves, Dow and Harper observed small dark red nodules on many of the

disease, be it "measles pneumonia," streptococcic "influenza" pneumonia or anaerobic pneumonitis; if bronchiectasis is a concomitant lesion or a sequel, the original disease was bronchopneumonia and the bronchiectasis has developed as the result of a series of pathologic events, originating in a bronchial lesion.

Once clinical symptomatic bronchiectasis has been established, pathologic examination of the bronchial tree reveals it to be the site of a chronic and subchronic bronchial and peribronchial inflammation. The mucosa of the dilated bronchi is either hypertrophic or atrophic. The epithelium may be intact, may have undergone mucoid degeneration or desquamation or may be replaced by stratified low cuboid, nonciliated or flat cells. The areas of hypertrophy may show a mucosa that is thickened, polypoid, infiltrated, velvety, granular or villous. The cellular infiltration involves not only the submucosa but also the deeper layers of the wall. This cellular infiltration is very dense and extends through the bronchial wall into the immediate peribronchial area. It is predominantly lymphocytic. This pathologic feature perhaps has an important bearing, as before mentioned, on the effect of radiation in chronic

observed over a period of many months at least and were known to have a chronic lesion with sustained high level of expectoration without spontaneous remissions. All the patients were rigorously investigated by means of bronchography and bronchoscopy, and the diagnosis of chronic bronchiectasis was thereby clearly established. The majority of the patients had been variously and unsuccessfully treated by bronchoscopic drainage and lavage, phrenic nerve operations and pneumothorax. They were treated finally by roentgen therapy as a last resort. The alternative in these patients was radical operative intervention such as lobectomy or pneumonectomy.

(a) *Diagnosis.*—It is of great importance to point out that chronic bronchiectasis is a diagnosis of exclusion. The term bronchiectasis, unless qualified, means a state of the bronchi—not a disease in the strict sense of the word. The diagnosis of bronchiectasis must be considered as incomplete and inaccurate unless one is able to diagnose the location of the disease (i. e., what lobe or lobes are involved) and the size and distribution of the dilatations. But of paramount importance it is necessary to ascertain the presence or absence of

Fig. 1.—Status after pneumonotomy for chronic lung abscess of right upper lobe and establishment of bronchocutaneous fistulas. Expectoration, from 8 to 12 ounces, with profuse, foul purulent drainage through fistulas.

Fig. 2.—Bronchogram showing dilated bronchi contiguous to drained chronic putrid lung abscess of right upper lobe.

Fig. 3.—Bronchogram showing status after roentgen therapy with reduction of expectoration from 12 ounces (foul) to 2 ounces (odorless) and very marked decrease in drainage. Showing constriction of previously dilated bronchi of right upper lobe. This result has been maintained for a follow-up period of three years.

bronchiectasis. The cellular infiltrated mucosa may have been changed to fibrous tissue and atrophy of the mucous glands, elastic tissue and cartilage may have occurred. The diseased wall may have been finally transformed into a thin fibrous, chronic inflammatory membrane. Usually atrophic and hypertrophic changes occur together.<sup>7</sup>

#### THE CLINICAL APPLICATION OF ROENTGEN THERAPY

Based on the foregoing outlined concepts of the action of roentgen radiation on the chronic inflammatory bronchial and peribronchial lesions and the mucus secreting bronchial epithelium, roentgen therapy in large dosage was instituted in a series of cases of chronic secreting bronchiectasis. No acute cases or cases with recent onset were treated. It is of considerable importance to be certain that a patient is not suffering from an ordinary superimposed acute infection of the upper respiratory tract which is making otherwise "dry" dilatations "wet." It is well known that bronchiectasis may be characterized by spontaneous remissions and exacerbations with seasonal variations. Therefore all the patients subjected to treatment were previously

various local features such as pulmonary tuberculosis, pulmonary abscess, bronchial foreign body, bronchial adenoma and bronchial carcinoma. The diagnosis cannot be made on the clinical history alone, suggestive as this may be. A clinical picture suggestive of bronchiectasis must always be substantiated by comprehensive positive bronchography and bronchoscopy. The bronchogram must be bilateral and map out the main branches on both sides. Bronchoscopy must enable one to rule out the presence of foreign body and new growth and permit one to observe which bronchi are discharging and are the sources of expectoration.

It is necessary to point out here that the important therapeutic consideration is not the bronchial dilatation but whether it is "wet" or "dry." Our use of roentgen therapy is not directed to cause morphologic alterations of the dilated bronchial tree but is directed to render a "wet" bronchiectasis "dry"; to cause an arrest of the symptom of expectoration, which, when copious and foul, makes the patient an abhorrence to himself. It is well known that extensive "dry" bronchiectasis can be present for many years without attracting attention clinically. The disproportion between the clinical symptoms and the bronchial dilatation in such "dry" cases may be striking.

**Pleural Form of Miliary Tuberculosis.**—Even states that the classic description of a pleural form of miliary tuberculosis credited to Empis is false, since the latter never described the clinical picture quoted and could not have done so since it does not exist. Even describes three cases of this condition and states retrospectively that the condition is probably more common than is generally realized. The condition is observed most frequently in adolescents and young adults. It is characterized clinically sometimes by rapid onset and sometimes by gradual development. There is a proved effect on the general state of the body contrasting markedly with the discrete nature of functional manifestations. The clinical and x-ray signs show a pleural effusion, either unilateral or bilateral and of relatively insignificant nature. Evolution toward death occurs in a few months, which may or may not be hastened by pericardial, peritoneal or meningeal complications. Anatomically the granulations are disposed most commonly on the serosa and the viscera and less in the lungs.

**Insulin Treatment of Periodic Vomiting.**—Since the effectiveness of insulin in the treatment of diabetic acidosis became well known, it seemed reasonable to attempt its use in periodic vomiting of infancy accompanied by acetonemia. Many contradictory opinions with regard to the rationale of this procedure have been reported, and Lelong briefly reviews some of these opinions. The coincidence of periods of vomiting with a state of acidosis has already been proved. However, this is not accompanied by any other signs of diabetes. Furthermore, there is an initial hypoglycemia, which fact would definitely contraindicate insulin during the initial phase of a vomiting crisis. However, hyperglycemia generally develops secondarily. These facts indicate that insulin should be given only in the prolonged phase of periodic vomiting and that insulin is contraindicated at the onset because of the initial hypoglycemic shock. The technic is not yet standardized. He believes that at present insulin therapy can be considered only as adjuvant to dextrose therapy.

- Pathogenesis of Cerebral Hemorrhage. J. Lhermitte.—p. 1843.

**Action of Streptococcal Toxin on Neurovegetative System.**—While recognizing the differences that must exist between the action of streptococcal toxins on the human body and on experimental animals, Gastinel and his co-workers report a study based largely on the guinea-pig. It is difficult to keep an active streptococcal toxin, since its activity is lost rapidly on storage. It is also noteworthy that marked differences of susceptibility exist between individual guinea-pigs. The method employed by the authors was the direct injection of scarlatinal toxin into the sympathetic trunk at various levels. Many were made into the left splanchnic nerve at its subdiaphragmatic emergence. The symptoms subsequently observed could be

grouped into an almost uniform scheme. After the injection the animals had a chill, followed five or ten minutes later by urine containing albumin, frequently accompanied by hematuria. The intestines of animals killed a few hours after a concentrated injection contained small amounts of albuminous and bloody mucus. During the subsequent days the animals became emaciated and often about the fourth or fifth day died suddenly if handled. Necropsy showed a striking diffuse red tint in the abdominal cavity. Vasodilatation was marked. Gastric lesions, purpuric spots, hemorrhagic erosions and infarcts were common. Similar pictures were found when other areas of the vegetative system were injected. At first glance these experimental results seem far removed from human scarlatina, but the action of the toxin on the sympathetic nervous system determines symptoms in the animal which are frequently found in scarlet fever and especially in its severe forms. The dominating modification seems to be the manifest electivity of the erythrotoxic toxin for the vegetative nervous system.

**Prostatic Cancer Metastases.**—Van Bogaert and his collaborators report an observation on a 44 year old man characterized clinically by pelvic and juxtaepelvic pains coming on by crises, which were especially severe at night. The disease progressed by exacerbations with fever and rapidly affected the general condition, causing anemia and loss of weight. From the biologic point of view there was a normal blood calcium and phosphorus, a low blood lipid level and a considerable increase in the blood phosphatase. The diagnosis, confirmed by microscopic study, was scirrhous carcinoma of the prostate invading the base of the bladder and causing metastases to all parts of the skeleton. The curious part of the case was the generalized osteoplastic reaction caused by the metastases. The most obvious explanation in the case reported is based on the increased phosphatase of the blood, which attained from eight to ten times its normal volume. The authors concluded that the osteoplastic form of prostatic metastasis is a subacute disease causing a rapid loss of weight and strength and sometimes febrile and painful symptoms. The roentgenograms produced can give rise to some therapeutic difficulty since the osteoplastic form is quite rare.

**Erythroplasia.**—Erythroplasia has been defined as a chronic disorder characterized by the appearance and persistence of red plaques, not painful or only slightly sensitive, accompanied by a slight infiltration of the exposed mucosa. Touraine and Solente review this subject. Ninety-two observations of the disease have been recorded, fifty-seven of them under the name "erythroplasia." The condition has apparently been observed in nearly all countries. It was found in fifty-eight men and twenty-eight women. It seems mostly to be a disease of the second part of life. In three instances it developed on a scar following trauma. The part played by syphilis seems to be important. Kraurosis and leukoplakia have been occasionally found coexisting. The site of predilection is the genital zone, and the disorder is much rarer in other mucous areas. In the majority of instances it is characterized by a single plaque which develops slowly and insidiously and passes unnoticed until there is a slight local itching. The flat, slightly raised and infiltrated surface of the lesion can usually be readily identified. It develops with extreme slowness first by simple hyperplasia and later by metaplasia. A malignant development always occurs eventually. The treatment of choice is electrocoagulation or the thermocautery. Recurrence must be guarded against.

- Lipoid Therapy and Lipolytic Ferments in Blood Serum. L. Franzi.—p. 1086.
- Presence of "Fleming's Lysin" in Human and Other Mammals' Milk. F. Martillotti.—p. 1097.

**Relation Between Measles and Tuberculosis.**—Carrara made a study of 1,470 children hospitalized in a pediatric clinic in connection with the problem of the relations between measles and tuberculosis. Measles does not predispose the organism to the development of tuberculosis. The rate of stimulation of latent foci and reactivation of healed tuberculous foci is low (11.2 per cent) except in children under the age of 5 years, in whom it is high. Measles has an unfavorable influence on the

lations and ulcerations. The exacerbations of symptoms during roentgen therapy possibly may increase this tendency. Five of our patients bled noticeably during treatment. "Radiation sickness" may be experienced that requires symptomatic treatment. The secondary anemia that may occur is combated with large doses of iron. Aggravation of symptoms and "radiation sickness" may necessitate protraction of treatment beyond three months. It is only after approximately three fourths of the treatment has been finished that noticeable improvement begins to take place. This is gradual and progressive, signalized by decrease in cough and foul expectoration. This improvement progresses

results. We are nevertheless including these partially treated patients in our series to give a full picture of our total experience to date.

The improvement that has been obtained in chronic bronchiectasis as the result of roentgen therapy, while moderate in some instances, has been so striking and remarkable in others as to render patients practically cough and sputum free.

It is perhaps necessary to emphasize here that the only criterion of improvement that we have employed is decrease in expectoration. It is the sole intention of the therapy to render a secreting "wet" bronchiectasis "dry"; i. e., to secure a symptomatic clinical cessation

TABLE 1.—Chronic Bronchiectasis Secondary to Chronic (Operated) Anaerobic Lung Abscess

Case	Lobes Involved	Duration of Symptoms	Expecto-ration in Ounces	Drainage	Technic of Treatment and Its Duration			Result on Expectoration and Drainage	
					Fields	Roent-gens	Days		
1	Right upper lobe, right lower lobe	3 yrs.	6-8	Profuse	5 ×	1,500	97	2 oz. odorless sputum, less cough	
2	Right upper lobe, right middle lobe, right lower lobe	7 yrs.	4-7	Profuse	3 × 3 ×	1,200 800	30	6 oz. sputum, moderate drainage, no change in condition	
3	Left lower lobe	1 mo.	1½-3	Fistula bleeding	3 ×	1,200	30	No expectoration or cough, fistula closed	
4	Right upper lobe, right lower lobe	1 yr.	½-1½	Bleeding fistula	5 × 2 ×	800 400	40	Closed wound, slight bleeding, cough, expecto-ration

steadily from week to week and continues for a period of at least four months after cessation of treatment, with gradual diminution of symptoms amounting in some cases to practical abolition of cough and expectoration.

#### COMMENT ON RESULTS

Our statistical summary of results must be considered tentative in the sense that it is based on a relatively small number of cases (thirty). A numerical presentation at the present time can be but an approximation of the figures that will be registered when a much larger number of cases have been treated. The cases in this series were consecutive and unselected and represent our total experience to date. Several of the patients now reported as but "moderately" improved or "unimproved" have not yet received full treatment to the entire known area of secreting bronchiectasis or have received but one course of therapy with but partial

of the main presenting features of the disease; namely, expectoration and cough. Those patients who have obtained great improvement in expectoration and cough and had experienced hemoptyses and episodes of pneumonia in the past have been free from these attacks and episodes subsequent to treatment. Clubbing of the digits has surprisingly subsided in a number of cases that have been improved. Unfortunately, this regression of clubbing cannot be demonstrated photographically at present as it was unexpected, and photographs of the hands of the patients in this series prior to therapy were not taken. Such photographs of hands are now being taken in the oncoming series of patients and will be presented at a later date.

Those patients who have responded to roentgen therapy have sustained their improvement during their entire follow-up examination to date, in some cases consisting of a period of over two years. During this

the 2,058 cases he was able to obtain information about the clinical course. A tabular report of the relationship between the type of bacillus and the clinical course indicates that in the district in which the author's studies were made 46 per cent of the cases with the grave type of the diphtheria bacillus took a mild course. In the mild and intermediate type of cases the mild forms of diphtheria amounted to 57 and 50 per cent, respectively. Of the cases with the grave type thirteen took a severe course compared to 5 per cent in the mild type and 6 per cent in the intermediate type. However, in sixty diphtheria fatalities, fifty-four cases were found to have the grave type of diphtheria bacillus and the remaining ones the intermediate type, the mild type being found in none of the fatal cases. The type differentiation has no therapeutic significance. It would be useless to give larger doses of serum in case of infection with the grave type than in the others. The decisive factor in the treatment is the time of administration of the serum. The frequency of the three types of diphtheria bacilli differs in different years and regions. With increasing duration of an epidemic, which frequently begins with one type, other types may appear and change the epidemiologic picture. There is no difference in the epidemiologic significance of the various types as regards the bacillus carrier, the ratio of grave to mild types being about the same in bacillus carriers as in diphtheria patients. The types of diphtheria bacillus are characterized by a high degree of constancy. If a different type appears in a patient, it is not the result of a change in type but rather of the new invasion of another type.

**Liver in Pathogenesis of Gout.**—Chrometzka discusses the various theories on the pathogenesis of gout. On account of the central position of the liver in the purine metabolism, he investigated how this metabolism would be changed following experimental impairment of the liver by the intravenous injection of india ink. By systematic injection for long periods, it proved possible to produce a fat cirrhosis of the liver in animals. In proportion to the impairment of the liver, the purine metabolism became impaired in that the animals gradually lost the capacity to oxidize uric acid. Necropsy revealed as the cause of this severe metabolic disturbance not only a cirrhosis of the liver but also a cirrhosis of the spleen and the adrenals, numerous uric acid concretions in the renal pelvis and uric acid needles in the punctate of a shoulder joint. After a detailed description of the histologic aspects, the author discusses the problem whether disturbances of the purine metabolism can be observed in hepatic diseases of human subjects and whether anatomic or functional disturbances of the liver can be demonstrated in persons with gout. He gives affirmative answers to both questions.

Criticism of Pneumothorax Therapy of Pulmonary Tuberculosis. F. Koester.—p. 1805.

\*Reflex of Differential Diagnostic Significance in Delirium Tremens. H. Schabelitz.—p. 1808.

**Spoon Nails.**—Rosegger shows that koilonychia (spoon nails) gained diagnostic importance when several authors called attention to the fact that this disorder concurs with a certain type of anemia; namely, achylic chloranemia. The abnormally concave nails appear contracted in the center and the edges are more or less turned up. The free edge of the nail is often extremely sharp, corresponding to the general thinning of the nail. Occasionally the free edge appears as if gnawed on. The usually lusterless spoon nails have a tendency to spontaneous tearing or lamellar splitting. These ungual changes do not always involve all the nails. Moreover there are milder degrees of koilonychia that are hardly perceptible to the eye and can only be felt, the nails being unusually flat (platonychia). In discussing the pathogenesis of koilonychia the author differentiates between exogenic and endogenic causes. The exogenic factors predominate in koilonychias that develop in persons whose hands are for long periods in hot soap suds and other cleansing fluids. Apparently the alkalis of the hot washing fluids cause a swelling and defatting of the nail, and

particles of the chemical remain under the rim of the nails. The mechanical factor involved in the washing process may likewise play a part, but the author thinks that individual predisposition is also a factor. In the further discussion of the exogenic causal factors he mentions the occurrence of spoon nails in persons whose hands are in frequent contact with oils, creosotes and cresols or in workers with coal. That exposure of the nails to acids or continuous wetting may play a part is proved by the occurrence of spoon nails in occupations that involve such exposures. As purely endogenic forms of koilonychia the author mentions their development in achylic chloranemia and certain cases of familial occurrence. The therapy of koilonychia varies according to the pathogenesis. In the occupational types, prophylactic measures are important. In the type that occurs in anemia, medication with iron is advisable.

**Differential Diagnosis of Delirium Tremens.**—Schabelitz points out that in case of delirium it may prove difficult to determine whether an infectious fever, abuse of alcohol or an endogenic psychosis is the cause. He directs attention to a reflex by which delirium tremens cases can be identified. This reflex was first described by Tramer in 1928. The author searched for this reflex in all patients (over a thousand cases) who were admitted to the institute for mental disorders with which he is connected. Tramer's reflex was elicitable almost exclusively in patients with delirium tremens, but in these it was observable again and again. The reflex is elicited by a blow of the reflex hammer on the ball of the foot. If the blow results in a single quick dorsal flexion of the foot, the reflex is positive. The most suitable position for the elicitation of the reflex is one intermediate between dorsal and plantar flexion and between internal and external rotation. Extremely flexed position or tension in the musculature of the leg prevents the reflex. The author observed that Tramer's reflex appeared in the majority of cases on the second day after the outbreak of delirium tremens and usually outlasted the so-called terminal sleep for hours or days. He never was able to elicit it within the first twenty-four hours.

**Chronic Nephritis.**—Vilks and Rabinovich report clinical observations on 100 cases of chronic nephritis over a period of from six to eight years. A careful analysis of the histories enabled them to establish that in fifty-five there had been an acute nephritis. In one third of the total no suspicion of acute nephritis in the past could be entertained. This type of nephritis gives a less favorable prognosis than those which follow an acute nephritis. Cases of chronic nephritis are not infrequently diagnosed as such late in the course of the disease. A considerable number of them are admitted for the first time with definite symptoms of uremia. The more prominent symptoms in the clinical picture are those of the cardiovascular system, such as insufficiency of the mitral or the aortic valves, cardiac asthma and attacks of stenocardia. Thirteen patients presented a picture that differed from the rest. These cases developed on the basis of an acute nephritis and rapidly progressed to invalidism and death. The recurring edema and high albumin content of the urine, lipoiduria, hypo-albuminemia and marked cholesterolemia of these cases presented a similarity to lipoid nephrosis. However, the presence of hematuria and a tendency to high blood pressure established that the basic process was a glomerulonephritis. The duration of life from the onset of acute nephritis in this group was from three to three and one-half years. The duration of chronic nephritis varies and may persist for decades.

**Treatment of Sepsis with Incompatible Blood.**—Spiridonov treated twenty-six cases of generalized sepsis with transfusion of incompatible blood. Sixteen patients presented

expectorating 16 ounces of foul sputum daily for a period of ten years, has been rendered practically asymptomatic for a follow-up period of two years. There were two deaths in this group while under treatment. One death occurred in a patient with profuse expectoration due to bronchiectasis which involved an entire hemithorax. After one course of roentgen therapy to the entire affected hemithorax a reduction of expectoration from 10 ounces to 2 or 4 ounces with complete loss of foulness was accomplished. Clubbing of the digits was on the wane and considerable symptomatic improvement occurred. A second course of roentgen therapy was instituted to reduce the residual expectoration. During the second course of therapy the patient experienced a severe hemoptysis followed by an extensive bronchopneumonia of the opposite healthy side, from which he died. Necropsy was not obtained. The second death occurred in a case of bronchiectasis involving the left upper and lower lobes with 8 ounces of foul sputum. Before the course of therapy was completed death occurred in another city. The cause of death could not be ascertained.

The follow-up examination on the improved cases has revealed, thus far, no recurrence in profuse expectoration with repeated infections of the upper respiratory tract and no tendency to resume foul expectoration. These patients who have responded markedly to roentgen therapy are no longer an abhorrence to themselves and to others. They appear clinically quite well, arrested to all practical purposes of their previous symptoms. One of the most severe cases in which great improvement has been experienced (16 ounce expectoration reduced to 1 ounce) has been, as already noted, followed for over two years without recurrence. The other cases that have been followed are of more recent date (from three to eighteen months). All our patients have been followed personally and have been examined at frequent intervals.

#### ROENTGENOLOGIC ASPECTS

In some of the cases that have been treated successfully, post-therapy bronchography has shown alterations in the picture of the dilated bronchial tree. The bronchi that were definitely dilated (saccular and cylindric), which were exposed to roentgen therapy, appear narrowed and strictured throughout after treatment (figs. 3, 5 and 6). It may be reasonably conjectured that such a change is due to healing by scar tissue of the previously ulcerated diseased bronchial tree. The end result is a contracture and stenosis of the diseased dilated bronchi throughout the area of treatment. In other cases, post-therapy bronchography, as yet, has shown no alterations in caliber of the dilated (now "dry") bronchi. Further studies in this regard are being carried out and will be presented in a future report. The morphologic type and degree of the dilatations (cylindric or saccular) has had no demonstrable relationship to the results of roentgen therapy. Roentgenograms of the chest other than the aforementioned bronchographic changes have shown no alterations after roentgen therapy. No evidence of pleural thickening, pulmonary fibrosis or mediastinal retraction has been noted.

#### CONCLUSIONS

1. Roentgen therapy in moderately large dosage as the sole method of treatment for chronic secreting bronchiectasis is feasible and successful, resulting in great symptomatic improvement in a considerable proportion of cases.

2. The clinical improvement in chronic bronchiectasis treated with moderately high dosage of roentgen therapy may be so great in many cases as to approach a practically complete cessation of the symptoms of expectoration and cough.

3. Follow-up examination over a period of two years in those cases in which there has been improvement has shown no recurrence of symptoms with infections of the upper respiratory tract.

## LIPOMA OF THE TONGUE

FERRIS SMITH, M.D.

GRAND RAPIDS, MICH.

Lipoma of the tongue is very rare. Mazzini<sup>1</sup> states that only one case occurred among 259,366 patients seen in his hospital during thirty-one years. This patient was a woman, aged 56. There are forty-four authentic

cases in the literature, to which the case reported here is to be added.

#### ESSENTIAL DATA CONCERNING THIS LESION

*Age of Appearance.*—It is difficult to determine at what age the tumor first manifests itself. It grows so slowly and is so devoid of any indication of its presence until its size produces mechanical disturbance that it goes unnoticed for many months. Age of incidence is indicated in twenty-seven cases. Six of these were congenital, one was noted at 3 weeks and the

Fig. 1.—The normal tongue presenting at the angle of the mouth represents the mid-point in the anterior posterior measurement of its dorsum. This point is clearly seen as a notch on the right border of the extended tongue in figure 3.

others appeared much later in life. The frequency increases with age.

*Sex.*—This tumor, like others of the tongue with the exception of the vascular ones, shows a distinct preference for the male. In the thirty-six cases in which sex is noted, twenty-three relate to men and thirteen to women. The ratio is quite different in the mixed types (fibrolipoma). Of the six cases recorded, five occurred in women.

*Origin.*—Malon, Butlin and Guelliot believe that the tumor originates from small masses of fat in the genio-glossus muscle and is slowly extruded as it gains in size. Bastianelli agrees with this opinion except in the cases of congenital tumors and those arising at the base. He believes that the latter originate in the abundant preepiglottic fat. Guelliot believes that trauma may determine the growth.

## ROENTGEN THERAPY FOR BRONCHIECTASIS

MAURICE BERCK, M.D.  
AND  
WILLIAM HARRIS, M.D.  
NEW YORK

In a preliminary report one of us<sup>1</sup> reported the effectual use of roentgen therapy for bronchiectasis in a case of chronic bronchiectasis. Here we report our successful experience in thirty cases of chronic bronchiectasis in which roentgen therapy was employed.

### ROENTGEN THERAPY IN BRONCHIECTASIS

Roentgen therapy has been employed for a great and protean variety of pulmonary inflammatory diseases. The literature is voluminous on the subjects of roentgen therapy for pulmonary tuberculosis, "postoperative pneumonia," "unresolved pneumonia," "chronic pulmonary suppuration," pertussis, asthma and chronic bronchitis.<sup>2</sup> Under the obscure headings of "chronic pulmonary suppuration" and "unresolved pneumonia," there were perhaps many cases of unidentified bronchiectasis. Roentgen therapy has been employed in small dosage by several authors for "unresolved pneumonia" and "chronic pulmonary suppuration" with varying and, for the most part, indifferent results. In all probability, many cases of unidentified bronchiectasis were previously included under those obscure headings. Experience many years ago in the radiotherapy department of the Mount Sinai Hospital with small dosage of roentgen therapy with so-called bronchiectasis demonstrated a total failure of effect. When the present work was begun the necessity of large dosage of roentgen therapy was stressed. Bronchiectasis, as it is now known, cannot be accurately or completely diagnosed without the use of bronchography and bronchoscopy.<sup>3</sup> Before the comparatively recent introduction of iodized oil, bronchography was not clinically feasible.<sup>4</sup> An accurate and unequivocal diagnosis of bronchiectasis is therefore a relatively recent accomplishment. It is perhaps for this reason that roentgen therapy has not been previously applied to the distinct entity of bronchiectasis. The deliberate and successful use of roentgen therapy in large dosage as the sole treatment of chronic secreting bronchiectasis has not, to our knowledge, been previously described or reported.

### RATIONALE OF THE USE OF ROENTGEN THERAPY FOR CHRONIC BRONCHIECTASIS

The use of roentgen therapy in chronic inflammatory processes, although resting largely on an empirical footing, nevertheless has a scientific basis of considerable clinical and experimental evidence. It is well established that x-rays act initially and mainly on the leukocytic (particularly lymphocytic) infiltration, causing destruction of these extraordinarily sensitive cells with ensuing phagocytosis and connective tissue proliferation as the sequelae of the action of the rays. In sub-chronic and chronic inflammatory processes this pathologic sequence acts to bring about a "resolution" of the chronic lesion.<sup>5</sup>

The early investigators of the action of roentgen rays on various organs reported that the lungs were relatively invulnerable to the action of the rays. However, the recent introduction of apparatus capable of delivering shorter wavelengths and larger depth doses has demonstrated that, within certain limits, definite tissue reactions can be produced in the lungs. It was the thought that an analogy might be drawn between the salivary glands and the bronchial mucous glands in their reactions to roentgen rays that led initially to this work on their use in bronchiectasis. Exposure of the salivary glands to roentgen rays brings about a diminution verging on abolition of secretion. It was thought that if a comparable reaction could be induced in the bronchial mucosa of bronchiectatic areas a comparable diminution of the secretion, and hence expectoration, might be expected. However, that such an effect can be produced in the bronchial mucosa of human beings, although supported by some experimental work on animals,<sup>6</sup> is problematic and perhaps unlikely. It is perhaps more logical to assume that the results which have been obtained in chronic bronchiectasis, as far as our present knowledge of the known reaction of tissues to roentgen rays can teach us, are due to the action of the rays on chronic inflammatory processes.

### PATHOLOGIC MANIFESTATIONS OF CHRONIC BRONCHIECTASIS

It is now accepted that the origin of bronchiectasis is based essentially on primary morphologic alterations of the bronchial wall. Extrapulmonary or pleural lesions probably play but a minor rôle in the causation of ectasia of the bronchi. Intrinsic bronchial disease must be present to bring about the weakening and destruction of elastic structure that permits the aerodynamic and hydrodynamic forces constantly acting on the bronchial lumen to operate to produce bronchiectasis. Regardless of the nature of the pulmonary

## ACUTE HEMATOGENOUS OSTEOMYELITIS IN CHILDREN

VERNON L. HART, M.D.

MINNEAPOLIS

There is apparently considerable confusion and disagreement among physicians regarding the treatment of osteomyelitis. Most of the difference can be explained on the basis that there are many types and various stages and, therefore, more than one method of treatment. A discussion of treatment should specify the type of osteomyelitis and the stage of the disease. There would be a more general agreement if this principle were followed instead of considering the entire subject.

The distinct entity to be considered in this paper is the acute stage of hematogenous osteomyelitis in children. The methods of treatment of chronic hematogenous osteomyelitis are separate and distinct problems. Likewise, the treatment of osteomyelitis, which is secondary to and a complication of compound fractures, amputations, empyema, felons, abscessed teeth, metal bone plates and screws, is based on different surgical and anatomic principles.

Acute hematogenous osteomyelitis is a local manifestation of a blood stream infection which is usually transient. The skeletal infection is always secondary to a remote infection, the source of which is usually the integument or the mucous membranes of the upper respiratory regions. A bacteremia necessarily precedes the localization of infection in the osseous system. Cultures of blood and pus demonstrate that the most common infective agent is *Staphylococcus aureus*. *Staphylococcus albus*, *Streptococcus pyogenes* and *pneumococcus* organisms are also frequent causative agents.

The first skeletal manifestation of the disease is constantly localized in a single metaphysis of one of the long bones of the extremities (fig. 2) or in the juxta-epiphyseal region of other bones of the growing skeleton. The primary bone involvement is not in the medullary cavity or cortex of the main shaft of a growing bone. During the early acute stage of the disease the infection is limited to a single metaphysis. However, subsequent to direct or hematogenous spread of the infection and in the subacute and chronic phases of the disease the main shaft, the neighboring joint and the medullary cavity may be affected. If the infection is not in the main shaft and medullary cavity during the acute stage there is no reason for their surgical exposure. The surgical attack should be limited to the site of the infection or metaphysis.

Robertson<sup>1</sup> of Toronto recently stated that:

The vital factors concerning the disease acute hematogenous osteomyelitis are not fully recognized by the medical profession. The disease has so long been regarded as actually what its name implies, that the diagnosis is not made in the early stages. If the disease were an infection of the medulla, as apart from the metaphysis, one would seek for signs of infection in the middle of the shaft. If these signs occur, they are extraordinarily rare. The early signs common to this disease are not to be found in the middle of the shaft. . . . The disease is so common, the symptoms so typical and the examination so definite, that one is surprised that the diagnosis is ever missed. I believe that if a case can be made for the seat of the infection being in the metaphysis, then the diagnosis will be very much simpler. The signs and symptoms all point to this.

## ANATOMIC FEATURES

The clinical history and pathogenesis of the disease and the fundamental principles of treatment are to a large measure explained by our knowledge of certain anatomic features of the bone and joint system.

Because of a difference in anatomy and physiology, a long bone of the growing skeleton is divided into segments: the epiphyses, the metaphyses and the diaphysis (fig. 2). The name "metaphysis" was first used by Kocher to describe the broad cancellous end of the diaphysis which is adjacent to the epiphyseal disk. The metaphysis represents the bone most recently developed from the epiphyseal cartilage or disk and is therefore more vascular, more delicate, more susceptible and less immune than the older bone of the shaft, which is dense and compact. The marrow of the shaft, which occupies the medullary cavity, is "bountifully provided with cellular elements," while the marrow of the metaphysis, which fills the interstices between the trabeculae of the cancellous bone, presents a "paucity of phagocyte cells."

The researches of Hobo<sup>2</sup> and Robertson seem to prove that the medullary cavity is much richer in phagocytic elements than the metaphysis. Fraser<sup>3</sup> recently stated:

I have a suspicion that in acute osteomyelitis the bone disturbance is but a local evidence of a general infection, and that the reason why the local infection is so constantly localized to the metaphysis is conceivably because we there encounter a concentration of reticulo-endothelial tissue, and that the local suppuration which results from the defensive activities of the area is in some measure protective against the general disturbance.

The cortex of the middle of the shaft is either more or slightly less than one-fourth inch (0.64 cm.) in thickness, while the cortex surrounding the metaphysis is much thinner, and near the epiphyseal disk it is paper thin (fig. 2). This is an important anatomic feature, since it explains the ease with which infection within the cancellous metaphysis may perforate into the subperiosteal space and why the rupture is usually juxta-epiphyseal, as emphasized by the late Dr. C. L. Starr.<sup>4</sup>

Fig. 1.—Subperiosteal hematoma involving the shaft of the femur of a child with infantile scurvy. The periosteum is firmly attached to the distal femoral epiphyseal disk and acts as a barrier against spread of a subperiosteal hematoma (or abscess) into the knee joint.

The nature of the blood vascular system of the metaphyses evidently plays an important rôle in the localization of infection in the cancellous juxta-epiphyseal region of growing bones. Lexer, Kuliga and Türk<sup>5</sup> in 1904 demonstrated the practically independent circulations of the epiphyses, the metaphyses and the

(b) *Classification of Patients Given Roentgen Therapy.*—Roentgen therapy was not instituted in any patient who presented acute inflammatory symptoms. The presence of active pneumonitis was considered a contraindication to the therapy. Only those patients who were ambulatory, afebrile and presented a chronic lesion with a more or less constant level of expectoration, without marked remissions, were considered suitable for therapy.

Accordingly, roentgen therapy was instituted in three types of chronic secreting bronchiectasis, namely:

1. Bronchiectasis secondary to chronic putrid lung abscess and residual symptomatically after pneumonotomy for the chronic abscess. These cases usually presented a profuse mucopurulent discharge from one or more bronchocutaneous fistulas at the site of pneumonotomy. Expectoration, if present, was of the same character as the discharge and usually varied from 3 to 6 ounces daily. The area of bronchiectasis was usually fairly extensive, comprising the greater part of the affected lobe, and not infrequently was multilobar. There were fourteen patients in this group (table 1).

Fig. 4.—Bronchogram: Oblique view illustrating extensive bronchiectasis from apex to base of left side. The normal bronchi of the healthy right lung appear on the right side of the film. Expectoration of 16 ounces of foul sputum; marked clubbing of fingers. Duration of disease, ten years.

Fig. 5.—Bronchogram showing contracture and narrowing of previously dilated bronchial tree of left side. This occurred after roentgen therapy that had succeeded in reducing expectoration from 16 ounces (putrid) to 1 ounce (odorless), accompanied by loss of clubbing of fingers. This result has been maintained for a follow-up period of two years.

Fig. 6.—Bronchogram: Oblique view after therapy of same case, showing stricturing of dilated bronchi after treatment. Compare with figure 4.

2. The second type of case was characterized by a bronchographic picture of involvement of one or two lobes, daily expectoration of from 1 to 5 ounces of non-odorous sputum, a minor degree or absence of clubbing of the digits and a history of relatively infrequent episodes of hemoptysis and pneumonitis. These patients did not appear very ill clinically; they were ambulatory and usually had never required hospitalization. There were three patients in this group (table 2).

3. The third group of patients appeared chronically ill. They were characterized usually by multilobar extensive bronchiectasis, frequent distressing cough with the expectoration of large quantities of foul sputum. They usually exhibited marked clubbing of the digits and gave a history of frequent hemoptyses and attacks of pneumonitis. There were thirteen patients in this group (table 3).

(c) *Method of Treatment.*—To secure "control" to the effect of the treatment, absolutely no other form of therapy was used coincidentally.

The patients were treated ambulatorily, for the most part, reporting to the radiotherapy department as "out-

patients." Roentgen therapy, in large dosage, was given to these patients over a period of approximately three months, all the diseased and secreting lobes (as revealed by thorough bronchography and bronchoscopy) being "cross-fired" through anterior, lateral and posterior fields. From three to seven fields were utilized as indicated. The average total dose used was approximately 1,200 roentgens through each of the anterior, lateral and posterior fields.

The physical factors of the technic are as follows: 180 to 200 kilovolts; focal skin distance, 50 cm.; current volume, 4 milliamperes; filter, 0.5 mm. of copper and 1 mm. of aluminum; size of field, 10 by 15 cm. Each treatment consisted of 75 roentgens, measured in air, to two or three fields.

The patients were treated usually two or three times a week. In bilateral cases one side (the most extensively diseased) was treated at a time, followed by the other side after the first course of roentgen therapy was finished. In a few of our earlier cases in which the dosage of roentgen therapy was inadequate and the result unsatisfactory, a second course was given after an

interval of four months. It was found that at least four months must be allowed to elapse after a course of therapy had been given to secure the full measure of improvement. In future bilateral cases it is our impression that it would be of advantage to treat the two sides simultaneously.

No significant skin changes due to therapy have been observed. Two children under the age of 12 years have been treated successfully.

It is very important to note here that during the course of treatment the patient's symptoms are exacerbated, sometimes to a marked extent. A low grade fever is common, cough is more frequent, and expectoration is more profuse. This is explicable on the basis of the action of x-rays. In our series, four patients experienced episodes of pneumonitis, occurring during the course of therapy. Whether this can be ascribed to the action of the rays is conjectural. Hemoptysis may occur during the exacerbation of symptoms. This occurred in patients who had previously experienced bleeding. Hemoptysis is normally very common in bronchiectasis and is usually due to bleeding granu-

throughout the life of the patient. The main issue in the treatment of the earliest phase of acute osteomyelitis should not be a consideration of the comparative values of the Carrel-Dakin, Orr,<sup>6</sup> Baer and other technics but rather of the necessity of adequate drainage of the affected metaphysis during the first twenty-four, thirty-six or forty-eight hours of the disease before the infection perforates the cortex or wall of the metaphysis near the epiphyseal disk, where it is paper thin, and before it spreads beneath the periosteum. The older textbooks taught that the usual course of spread of the infection was directly from the cancellous end of the bone or metaphysis into the medullary cavity. This may occur, but the common course of spread of the infection, as first emphasized by Starr, is by perforation through the extremely thin cortical wall of the metaphysis adjacent to the epiphyseal disk. The infection then spreads beneath the periosteum along the shaft of the bone, which it invades through the haversian system. When there is evidence of a subperiosteal abscess the disease has passed beyond the phase that I refer to as acute hematogenous metaphysitis.

The term acute hematogenous metaphysitis should be added to the terminology of the study of osteomyelitis because it defines that phase of acute hematogenous osteomyelitis when surgical treatment may cure the disease without necrosis and sequestration of bone. The term will help to focus the attention of physicians on the metaphyses of the growing skeleton when considering cases presenting acute infection. It may also stimulate a more general interest in the anatomy, physiology and clinical significance of the metaphyses.

Acute hematogenous osteomyelitis or metaphysitis is preeminently a disease of childhood and puberty when the metaphyses are extremely vascular. The late adolescent skeleton is infrequently affected by the disease and the adult skeleton rarely because the vascularity of the metaphyses is diminished subsequent to the period of greatest physiologic activity of the epiphyseal cartilages or disks. Acute osteomyelitis in infancy, as recently reported by Green,<sup>7</sup> "differs in so many respects from osteomyelitis in older children that a separate consideration of the disease in children under 2 years of age is desirable."

The disease is definitely more common in boys than in girls, and this is because boys are more subject to trauma, exposure and infection of the skin and upper respiratory regions.

Only a single metaphysis is affected at the onset of the disease, but after the first twenty-four to thirty-six hours it is common to see another bone lesion occurring. Infrequently the primary bone infection may localize in a center of ossification of one of the epiphyses. If the invading organism is very virulent and the general and local resistance of the patient extremely low, the infection may be overwhelming from the onset. Several bones may be involved simultaneously, and an early death occurs in most cases owing to a general septicemia with localization of the infection in vital parts.

An analogy between acute appendicitis and acute metaphysitis is a sound one, since the tragic complications of each disease are the result of perforation. Today it is general knowledge among the public that the proper treatment of acute appendicitis is appendectomy during the early phase of the disease before

rupture of the appendix. The medical profession should continue its efforts to inform the public regarding the tremendous importance of early diagnosis and treatment of acute hematogenous metaphysitis before perforation of the cortex of the affected metaphysis. A subperiosteal abscess may be compared with peritonitis, since both are pathologic processes secondary to perforation. Many patients do not seek the advice of a physician until several days after the onset of symptoms, which may have been masked by the administration of drugs. Physicians should be alert to the necessity of diagnosis and surgery before perforation of the metaphyseal cortex and to the consequences of procrastination.

#### CLINICAL MANIFESTATIONS

During the earliest clinical phase the child is acutely ill and complains of constant severe pain in the region of a joint. Movements of the affected extremity, pressure and the application of heat aggravate the pain. The integument over the involved region does not present any striking changes and the contour of the extremity is not altered. Marked swelling, edema and redness are not present. These changes may appear one or several days later and are evidence of perforation of the infection through the cortex of the affected metaphysis. Point tenderness is one of the most important clinical observations. It is extreme and definitely localized over a limited area of the involved metaphysis. The adjacent joint is clinically normal when examined gently and carefully, although there may be limitation of movements. Synovitis and effusion are not observed during the earliest phase of acute hematogenous osteomyelitis when the infection is confined within the metaphysis. The physician should not examine the extremity for tenderness until the manual examination has been completed. Increased pain; lack of cooperation and muscle spasm usually follow the demonstration of tenderness. The chief complaint is incessant pain in the neighborhood of a joint and the chief sign is severe, unchangeable tenderness, which is localized over the affected metaphysis.

The patient presents signs of intense toxemia. The temperature is elevated to 102-104 F. and the pulse rate is rapid, from 120 to 130 per minute. Blood examination reveals a high polymorphonuclear leukocytosis, usually up to 25,000 or 30,000. Blood cultures should be done as a routine and the urine should be examined for Hedri's sign or the presence of lipuria.

A careful investigation of the history of the patient frequently reveals that trauma may have played an important rôle in the localization of the infection. The type of injury is generally a metaphyseal strain.

Radiographic studies of the involved bone and neighboring joint are negative for any evidence of infection during the phase of acute hematogenous osteomyelitis. Acute osteomyelitis does not cause enough cortical change to be recognized by the x-rays until the tenth to the twelfth day.

#### PATHOGENESIS

The pathologic changes within the metaphysis are identical with those in soft tissues which are combating a pyogenic infection. The clinical manifestations, however, are different, since the infection is confined within a bony structure which does not yield to pressure resulting from the combat between the infection and the defensive mechanisms until the "bone furuncle" perforates the metaphyseal cortex and spreads beneath the overlying periosteum. The abscess usually makes its

abscess.<sup>8</sup> Five of the improved patients (table 1) have been followed for a period of approximately two years. They have maintained their improvement to date with-

death occurred in another city three months after the last treatment to the right lower lobe. The cause of death could not be ascertained.

There were three patients with chronic bronchiectasis characterized by moderate amounts of nonfoul expectoration (table 2).

There were thirteen patients with chronic bronchiectasis characterized by profuse foul expectoration (table 3). These patients with multilobar bronchiectasis and profuse expectoration of large quantities of foul expectoration, although the most seriously ill, have experienced the greatest benefit and have shown the most striking results and remarkable improvement. In some of these patients the bronchiectasis involved an entire hemithorax from apex to base, and in some the lesion was bilateral. Reductions in daily expectoration from as high as 16 ounces to 1½ ounces have been accomplished with complete loss of foul odor. Cough, previously harassing, has been reduced to a short morning bout with an expectoration of approximately 1 ounce. Concomitant with their great symptomatic improvement, some of these patients have lost the clubbing of their fingers. The episodes of pneumonitis have not recurred.

It is noteworthy that this type of bronchiectasis presents a pathologic and clinical picture that is more markedly inflammatory in its nature than the other two groups of patients. The marked beneficial reaction of

out recurrence of previous symptoms of profuse drainage through fistulas and profuse expectoration. The other cases are more recent. The death in this group occurred in a case in which all three lobes on the right side were involved in a chronic bronchiectasis secondary to a chronic anaerobic lung abscess. The daily expectoration was 4 ounces of foul sputum. Only partial treatment had been given (to the right lower lobe) and

roentgen therapy in these patients could, with logic, be ascribed to the effect of roentgen therapy on chronic inflammatory processes, as noted in the previous section in which the action of roentgen rays is discussed. This impression of more marked benefit derived from the treatment may have been gained because this group of patients presented an intensity of symptoms greater than that present in the first two groups. Thus the abolition of foulness, the practical cessation of cough and profuse expectoration and the loss of clubbing were more obvious and striking. One of these patients,

8. We are indebted to Dr. Harold Neuhoef for permission to treat this group of patients, who had been operated on in his surgical service at Mount Sinai Hospital.

shaft and medullary cavity should not be attacked with chisel and mallet. Too frequently a radical saucerization or gutter operation is performed on the main shaft of the bone. The marrow of the medullary cavity is exposed and it may even be described as "pus." Starr was the first physician to teach the fact that the medullary cavity is not infected as a rule during this phase of the disease.

The primary bone abscess is in the metaphysis, which is the source of the subcutaneous or subperiosteal abscess. Therefore, chisel and mallet or drill may be used to enlarge the opening in the cortex of the metaphysis through which the infection had perforated and spread beneath the periosteum. Infrequently the medullary cavity may be filled with pus. Therefore a relatively large drill hole, about three-eighths inch in diameter, should be made through the cortex into the medullary cavity a short distance on the diaphyseal side of the infected metaphysis. If pus escapes, several similar drill holes should be made along the infected diaphysis for adequate drainage of the medullary cavity. Pus will be found infrequently in the medullary cavity; however, I believe that in the presence of stripping of the periosteum a drill hole should be made directly into the medullary cavity as a routine. It can do no harm and gives important information.

The wound is lightly packed (Orr method) with petrolatum gauze and covered with sterile dressings and sheet wadding. A plaster-of-paris cast is applied for the dual purpose of physiologic rest and prevention of deformity. Again, as already stated, the physician should anticipate continuation of signs and symptoms of a general blood stream infection. The persistence of clinical signs of severe infection should not tempt the surgeon to perform unsound and radical gutter operations on the shaft and medullary cavity. If the primary bone lesion involves the proximal femoral metaphysis or femoral neck region, in this stage of the disease the hip joint is invariably infected. Surgical drainage of both metaphysis and joint is indicated.

Involvement of the distal metaphysis of the fibula at this stage with stripping of the periosteum from the shaft by a subperiosteal abscess also presents a variation from the usual treatment. Diaphysectomy is definitely indicated, since the fibula is a non-weight bearing bone and function of the extremity is compatible with loss of substance from the fibular shaft. The diaphysis should be removed as far as the periosteum is stripped by pus. Great care must be exercised during the dissection in order that the common peroneal nerve is not injured. Diaphysectomy is indicated in this stage of the disease in any long bone that can be sacrificed without loss of function to the part.

In all cases the wound should fill in with granulation tissue from the bottom and the walls should not be permitted to come in contact. To accomplish this and to control odor the petrolatum dressings should be changed about every ten or more days.

Many patients will gradually pass into the chronic stage of the disease. Spread of infection, vascular damage, necrosis of bone, sequestrum formation and deformity will determine the subsequent surgical program.

#### CONCLUSIONS

1. The first skeletal manifestation of acute hematogenous osteomyelitis is localized within a single metaphysis.

2. The primary bone involvement is not in the cortex of the main shaft and medullary cavity.

3. Acute hematogenous metaphysitis is a distinct clinical entity. It represents the earliest clinical phase of acute hematogenous osteomyelitis when the infection is confined within the interior of the affected metaphysis. It is during this period that proper surgical treatment may prevent extensive osseous and joint involvement, necrosis and sequestration of bone.

4. Radical gutter operations on the cortex of the main shaft and medullary cavity during the acute stage of the disease are surgically and anatomically unsound.

5. Dehydration should be prevented and controlled if present.

6. The surgical treatment includes conservative but adequate metaphyseal drainage. The surgical principles are based on the fundamental clinical and pathologic investigations of the late Dr. C. L. Starr.

7. The pathogenesis of the disease is determined by anatomic features of the bone and joint system.

8. The moment the infection perforates the cortex of the metaphysis and spreads beneath the periosteum, the prognosis as to morbidity is critically altered.

9. Acute hematogenous osteomyelitis is divided into two stages. The first stage is before and the second stage is subsequent to perforation of the thin cortical wall of the affected metaphysis. The clinical and pathologic changes, treatment and prognosis of the two stages are distinctly different.

## THE CENTRAL ACTION OF BETA-AMINOPROPYLBENZENE (BENZEDRINE)

### CLINICAL OBSERVATIONS

M. H. NATHANSON, M.D.

LOS ANGELES

Beta-aminopropylbenzene (benzedrine) is a compound of the epinephrine series resembling ephedrine in chemical constitution, as shown in the structural formula. In 1910 Barger and Dale<sup>1</sup> made an exhaustive study of a large group of epinephrine-like substances, with the conclusion that an action simulating that of true sympathetic nervous stimulation is not peculiar to epinephrine but is possessed by a large number of amines (substituted ammonias). These substances were termed sympathomimetic amines by Barger and Dale, since they mimic the effects of sympathetic stimulation. The response of the blood pressure in experimental animals has been used largely to study the comparative activities of these compounds. More recently I have studied the comparative actions of these substances on the cardiac standstill which may be induced in many individuals by pressure over the carotid artery in the neck.<sup>2</sup>

Interest in these compounds has centered almost entirely on the sympathomimetic action, an effect on the peripheral nervous system. This action is responsible for the dilatation of the pupils and bronchi, for vasoconstriction and the pressor effect, and for the cardiac stimulation. With the rediscovery of ephedrine in 1923 it was found that, in addition to the peripheral action, certain of these compounds have a stimulating effect on

Virchow and Colombo<sup>2</sup> believe that the tumor results from a metaplasia of the connective tissue which separates the muscle bundles following the deep vessels and nerves.

Pozzi distinguishes the origin of the submucous from the intermuscular types. The former originate immediately below the mucosa in the same manner that lipomas appear beneath the skin, the fat cells in the two locations being similar.

**Geographic Location.**—The tumor occurs most frequently on the edges of the tongue. It also occurs at the base and, rarely, on the tip. Of the forty cases in which the tumor is located, it occurred on the edges in twenty-two, on the base in eight, on the tip in five and on the "back" of the tongue in the remainder.

**Histologic Location.**—The tumor may be submucous, interstitial or intermuscular. The interstitial tumor is recorded in only three cases. It occurs in the submucosa most frequently.

Fig. 2.—Distortion of the lips and cheeks.

Fig. 3.—Appearance of tongue sixty days after removal of tumor.

Fig. 4.—Readjustment of lips and cheeks.

**Character.**—The tumor is benign. It varies from the size of a grain of rice to that recorded in this case. It is rarely multiple. It may be round, ovoid or lobulated. The ovoid tumor generally elongates parallel with the long axis of the tongue.

Adipose tissue predominates in most tumors. Intermuscular tumors are usually encapsulated. In some instances there is more connective tissue, characterizing the tumor as a fibrolipoma.

The rate of growth is very slow. One reporter records that a tumor grew from the size of a "grain of rice to the size of a grape in two years"; another that the growth reached the size of a walnut in three years; another that the growth extended from the cecal foramen to the lingual tip in fourteen and a half years, and so on. Our patient first noticed a small mass on the right tip of the tongue seventeen years prior to our examination.

The tumor is covered with smooth, thin, transparent mucosa which is usually devoid of papillae. The

included fat gives the mucosa a characteristic color variously described as "rose," "straw" or "yellowish gold." It is usually soft, giving a pseudofluctuation, or hard in proportion to the connective tissue element. The intermuscular tumor is fixed, in contrast to the mobile submucous lesion. It may or may not be pedunculated. It may become ulcerated.

**Diagnosis.**—The characteristics and history noted determine the diagnosis. Marked pseudofluctuation may require an aspirating needle for exclusion of the various cysts.

**Treatment.**—Complete removal is without danger and produces a definite cure.

#### REPORT OF CASE

Mrs. G. P., aged 45, examined Jan. 22, 1934, presented a mass the size of an orange on her tongue.

She stated that she had first noted a mass the size of a pea on the right tip of her tongue seventeen years previously. Nine years later the mass had reached such a size that she had to

discard her dentures and take soft foods only. She was "treated by a quack cancer specialist without relief" two years later. During the past six years she had remained at home "expecting to die from her cancer."

The tumor was round, shiny, smooth, slightly translucent and moderately pseudofluctuant. It involved the tip and largely replaced the muscle of the right anterior half of the dorsum. The covering had the appearance of a modified squamous epithelium.

The circumvallate papillae and the upper third of the epiglottis were plainly visible as the result of the prolonged traction. The tumor could be pushed through a much enlarged mouth into greatly distended cheeks. Note the lower lip in figure 2.

The tumor was removed under local anesthesia January 30.

A flap of the epithelial covering was raised from the anterior third of the tumor and the mass was resected. The left half of the tongue was employed to repair the loss on the right side with a moderate foreshortening which interferes with neither speech nor function. Figures 3 and 4 show the result sixty days later. Note the readjustment of the lips and cheeks.

The histologic report was "simple lipoma." The mass weighed 320 Gm. and measured 11 cm. by 9 cm. by 7 cm. This is the largest of these tumors reported in the literature.

Wealthy Street at Plymouth Road.

2. Colombo, Angelo: Lipoma della lingua, Tumori 18: 233-261 (May-June) 1932.

usually mild and of short duration. It was necessary to discontinue the drug in but three patients: in two, owing to disturbed sleep and in one instance because of severe palpitation.

#### SUBJECTIVE EFFECTS IN NORMAL INDIVIDUALS

The patients uniformly noticed that the various effects appeared in their maximum intensity soon after

#### *Questionnaire Used in the Study of the Action of Beta-Aminopropylbenzene Sulfate in Eighty of the Resident Hospital Staff and Laboratory Technicians*

The purpose of this experiment is to determine the type and degree of reaction following the administration of the tablets. It is hoped that you will make a careful analysis of the physical and mental reactions which may have occurred during the day of the experiment. If any reaction is observed it is desirable that an approximate estimate of the intensity of effect be noted and expressed as follows: 1 plus indicates a mild reaction; 4 plus an intense effect and intermediate degrees expressed as 2 plus or 3 plus. It is best to compare your physical and mental state on the day of this experiment with that of the usual day.

1. Any evidence of increased energy, increased desire or capacity for work?
2. Reaction to day's work as regards fatigue?
  - a. Less fatigue
  - b. Increased fatigue
  - c. No effect.
3. Many normal individuals feel tired at certain times of the day. If this is a frequent reaction in you, has it in any way been modified today?
4. Have you been more talkative?
5. Dryness of mouth?
6. Sweating?
7. Appetite: Less? More?
8. Effect on sleep (this should be answered on the following morning).
9. Any evidence of the following:
  - a. Euphoria (sense of well being)
  - b. Feeling of exhilaration
  - c. Depression
10. Mental activity: as you look back over the period following the tablets, have you observed any effect on mental processes? Has there been any indication of increased mental efficiency or any evidence of clouding of mentality?
11. Any other reaction should be noted such as headache, nausea, tremor, palpitation or any effect not mentioned.
12. If any reaction occurs, note if possible the approximate time of onset and duration

Name.....  
It is important that the name be signed, as the type of tablet administered will otherwise not be known and the record would be worthless.

the initial dose of the beta-aminopropylbenzene sulfate. It therefore seemed interesting to study the subjective reactions of a large group of normal subjects following a single administration of the drug. For this purpose a group of young individuals, consisting of the resident hospital staff, technicians and student technicians, was used. The drug was administered in two ways: (1) in divided doses, 1 tablet (10 mg.) before breakfast, and a second tablet before the noon meal, and (2) a single dose of 20 mg. before the noon meal. The study was made on eighty individuals, of whom fifty-five received the drug and twenty-five were given tablets of the same appearance containing lactose. Each subject received a questionnaire in a sealed envelop with instructions to open the envelop and answer the questions as carefully as possible in the evening.

The accompanying tabulation shows the contents of the questionnaire and the reactions are summarized in the table. There was a great variation in the intensity of the reaction but in only eight instances was the response so minimal as to be considered questionable. The most frequent effect was a sense of well being and a feeling of exhilaration, and this occurred in more than two thirds of the subjects. Next in order of frequency was a lessened fatigue in 62 per cent, talkativeness in 56 per cent, and increased energy and capacity for work in 54.5 per cent.

Some of the expressions that were used were the following: "increased energy, felt as if I could not get places fast enough"; "had no feeling of usual fatigue"; "usually tired at dinner time, resumed work after dinner and continued until 10 p. m. and no fatigue"; "I have done things today I usually dislike but which I rather enjoyed doing today"; "the last hour and a half of work is usually an effort, today I felt fine"; "my usual after lunch slump was appreciably reduced"; "did not have my usual lethargic period after lunch"; "sense of well being, nothing seemed impossible of accomplishment"; "I wanted to stop and talk to everybody I met"; "I found myself entering into conversation with donors who came to the laboratory for tests"; "I felt unusually friendly toward other people"; "my spirits have been high all day, felt bubbling inside"; "this is a few days before the menstrual period and in the last two days I had my usual premenstrual depression; today this was all gone"; "had feeling of being very efficient"; "I was able to organize my work quickly and efficiently"; "my mind felt clear all day."

Most of the subjects who experienced these favorable reactions also noted some effects which were mildly unpleasant. There was no relationship between the favorable and the unpleasant effects. In some instances an unusually favorable response was associated with minimal unpleasant effects and in an occasional subject the undesirable effects predominated. The unpleasant reactions were usually of a mild degree and rather transient. The most frequent were dryness of the mouth, sweating, lessened appetite, and a disturbance in sleep. In a smaller number tremor of the hands was noted in sixteen instances, palpitation in eleven, slight headache in eleven, nausea in five, and dysuria in four. The incidence of unpleasant reactions seemed higher in this group than in the series of patients discussed in the earlier portion of this report. This may be explained by the more advanced age of the latter group, since it was observed in several instances that older persons seemed to tolerate more and require more of the drug for a therapeutic effect.

#### *Summary of the Reactions of Fifty-Five Members of the Resident Staff and Laboratory Technicians After the Administration of Twenty Milligrams of Beta-Aminopropylbenzene Sulfate*

	Number	Per Cent
Increased energy, desire and capacity for work.....	30	54.5
Reaction to work as regards fatigue		
(a) Less fatigue.....	34	62.0
(b) Increased fatigue.....	10	18.0
(c) No effect.....	11	20.0
Usual period of exhaustion abolished.....	21	38.0
More talkative.....	31	56.0
Euphoria and feeling of exhilaration.....	37	67.0
Depression.....	4	7.0
Mental activity and efficiency		
(a) Increased.....	23	42.0
(b) Diminished.....	2	3.0
Dryness of mouth.....	24	44.0
Sweating.....	27	50.0
Appetite		
Less.....	27	50.0
Better.....	5	9.0
Insomnia (usually mild to moderate).....	17	30.0

In twenty-four of the questionnaires, statements were made relative to the time of onset of the effects and the duration. There was more certainty and consistency as to time of onset. Most of the effects were noted from thirty minutes to one hour after the ingestion of the drug. There was less certainty as to duration of

cortex of the shaft. The metaphysis is richly supplied by the terminal branches of the nutrient artery. The vascularity of the juxta-epiphyseal region is abundant and consists of a bed of terminal capillary loops where the blood current is slowed and where infection is very likely to settle as a bacillary embolism. The nutrient artery also supplies the medullary cavity and endosteum and freely anastomoses with the periosteal vessels, through the haversian system, which are the main

Fig. 2.—Diagram illustrating the usual course of spread of infection in acute hematogenous osteomyelitis. X represents the point of firm attachment of capsule and periosteum in the region of the epiphyseal disk when the metaphysis is extracapsular. Y is the fixation point of capsule and periosteum when the metaphysis is intracapsular.

sources of nutrition to the cortex of the entire shaft. Epiphyses receive their blood supply from articular and cortical arteries. The epiphyseal circulation is separated from the vascular system of the metaphysis by a practically avascular barrier, the epiphyseal disk. The extraordinarily rich capillary network of the metaphysis and juxta-epiphyseal region is gradually reduced with diminished physiologic activity of bone production of the epiphyseal disk. This explains why acute hematogenous osteomyelitis is essentially a disease of childhood and puberty.

The periosteum completely covers the shaft of a long developing bone and is firmly attached, except in a few instances, to the entire circumference of both proximal and distal epiphyseal disks. The ease with which the periosteum is stripped from the cortex of the shaft of a growing femur and the barrier that it provides against involvement of the knee joint because of its continuity with the distal femoral epiphyseal disk is demonstrated by the radiographic study of a subperiosteal hematoma resulting from infantile scurvy (fig. 1).

The problem of joint involvement secondary to acute hematogenous osteomyelitis depends largely on the anatomic relationship between the joint capsule, the periosteum, the metaphysis and the epiphyseal disk (fig. 3). Certain metaphyses are intracapsular (hip) while others are either entirely extracapsular (ankle) or

intracapsular and extracapsular (shoulder). When a metaphysis is intracapsular the periosteum no longer protects the joint from involvement, since the greater portion of the periosteum is attached to and blends with the capsule instead of with the epiphyseal disk. Perforation of the intracapsular metaphyseal cortex and its thin periosteal covering permits the infection to invade the joint cavity directly. The metaphysis of the proximal end of the femur is completely intracapsular. This anatomic feature explains why infection of the hip joint is the rule in acute hematogenous osteomyelitis of the proximal end of the femur. Perforation of the distal tibial metaphyseal cortex does not invade the ankle joint directly, since this metaphysis is entirely extracapsular. Clinical experience teaches one that infection of the knee joint is an infrequent complication of acute hematogenous osteomyelitis of either the distal end of the femur or the proximal end of the tibia. Most rigid knees that one does observe are more often the result of extra-articular adhesions and contractures than intra-articular infection.

Surgeons must have a thorough knowledge of the anatomic relationship between metaphysis, epiphyseal disk, periosteum and joint capsule in the many regions of the skeleton, since surgical drainage of acute hematogenous osteomyelitis without joint infection should always be made through an extracapsular dissection. The order of frequency of involvement of the metaphyses and juxta-epiphyseal cancellous bone of the growing skeleton is as follows: proximal end of tibia, distal end of femur, distal end of tibia and fibula, proximal end of femur, ilium, proximal end of humerus, distal end of radius, and distal end of humerus. No bone, however, is exempt.

#### CLINICAL PATHOLOGIC FEATURES

The earliest clinical phase of acute hematogenous osteomyelitis is in fact an acute hematogenous metaphysitis, when diagnosis is rarely made and surgical treatment more rarely performed. The incidence of chronic osteomyelitis will be lessened when physicians attack the primary bone infection within the metaphysis before it perforates the metaphyseal cortex and involves, either by direct or by hematogenous spread, the cortex and medullary cavity of the shaft of the affected bone,

Fig. 3.—Drawings which illustrate the importance of the anatomic relationship of metaphysis, epiphyseal disk and joint capsule in determining joint involvement in acute hematogenous osteomyelitis.

neighboring joint and other regions of the skeletal apparatus. The infection remains localized in the metaphysis or juxta-epiphyseal region for a period of hours or several days, depending on the virulence of the invading organism and the local and general resistance of the patient. It is during this very brief period when the infection is confined to the interior of the metaphysis that diagnosis is essential and metaphyseal drainage imperative if one is to avoid a surgical catastrophe or chronic osteomyelitis with recurrent disability

Mount Sinai Hospitals  
CHICAGO

The clinical importance of intra-uterine rings complicating labor is not sufficiently appreciated. This condition, which causes dystocia, is chiefly functional and has been designated by at least twenty different terms. The assumption that intra-uterine rings are due solely to the contraction ring of Bandl, the contraction ring of Schroeder or the retraction ring of Barbour and Lusk is not tenable, in view of the different uterine levels at which they are found. The designation of this dystocia as a constriction ring dystocia is based on biologic grounds. A review of 350 cases collected from the literature and twenty-one cases in my experience demonstrates that a conservative management with delivery by vagina is the safest for the mother and child.

## THE FORMATION OF INTRA-UTERINE RINGS

The physiologic division of the uterus into an upper and a lower uterine segment was definitely established by the second stage frozen section of Braune<sup>1</sup> in 1872. Bandl<sup>2</sup> emphasized and popularized the occurrence of this ring in labor, with the result that the designation ring of Bandl is used for normal and abnormal labors. Schroeder<sup>3</sup> pointed out the zone of demarcation between the two segments occurring in normal labor and called this zone the "contraction ring." Barbour<sup>4</sup> and Lusk<sup>5</sup> designated the zone of demarcation between the two segments occurring in normal labor the "retraction ring." The criteria of these observers were based on longitudinal changes but no evidence was presented of the property of transverse contraction at any level.

Comparative anatomy and physiology of the lower animals studied by Ivy, Hartman and Koff<sup>6</sup> and Rudolph and Ivy<sup>7</sup> demonstrate the physiologic property of constriction rings or zones having the property of transverse contraction. Bumm<sup>8</sup> has presented a specimen of a postpartum human uterus which shows intra-uterine transverse rings or zones in the upper and lower uterine segment, which resembles the postpartum uterus of the dog.

A ring is not demonstrated by external inspection in cesarean sections but is found only after the hysterotomy when difficulty is encountered in attempting to extract the fetus from the uterine cavity. The ring is found behind the symphysis pubis and below the firm attachment of the peritoneum on the anterior uterine wall. Gilliatt<sup>9</sup> reported fourteen cesarean sections for

intra-uterine rings in which the constriction ring was found to be about 1 inch (2.5 cm.) below the physiologic retraction ring.

Clinical experience demonstrates that the majority of intra-uterine rings are located behind the symphysis pubis. In my experience I have found the intra-uterine rings to be located behind the symphysis pubis and about 7 or 8 cm. above the external os. That intra-uterine rings are at or near the internal os is the opinion of Duncan,<sup>10</sup> Kehrer,<sup>11</sup> Veit,<sup>12</sup> Berkeley,<sup>13</sup> Polak<sup>14</sup> and Barbour.<sup>15</sup>

For this discussion, I shall assume, first, that the physiologic retraction ring at the onset of labor is found at the level of the superior border of the symphysis pubis, where I have observed it during the performance of elective cesarean section and where it has been observed by Smyly,<sup>16</sup> Lahs<sup>17</sup> and Reynolds<sup>18</sup> and, second, at the onset of and during the normal second stage of labor the physiologic retraction ring rises, so that it is from 6 to 8 cm. above the symphysis pubis.

It should also be pointed out, before discussing the location of the ring, that comparative physiology demonstrates that the fundal ring in the dog and sheep has the property of contraction and relaxation. The constriction rings or zones in the dog and rabbit have the property of contraction and relaxation. The physiologic retraction ring in the monkey has the property of contraction and relaxation. The fundal ring of the nongravid horn of the cow and sheep relaxes after the expulsion of the products of conception, and in the gravid horn the fundal ring reappears with labor and the musculature undergoes retraction.

## LOCATION OF THE CONSTRICTION RING

The site of the constriction ring as related to the symphysis pubis is shown in table 1. Since in 75 per cent of the cases the ring is behind the symphysis pubis, from the foregoing data it must be assumed that the physiologic retraction ring is not the site involved.

TABLE 1.—Location of the Constriction Ring

A. Palpable internally in 248, or 91%
1. Around the fetal neck, behind the symphysis pubis, in 186, or 75%
2. Around the body of the fetus, above the symphysis pubis, in 39, or 14%
3. Forelying (in front of the presenting part) behind the symphysis pubis, in 23, or 9%
B. Palpable externally in 24, or 9 per cent

The confusion concerning terminology, especially of the junction between the upper and the lower uterine segments, will be briefly discussed.

1. *The Physiologic Retraction Ring.*—Since the junction between the two uterine segments is due to physiologic changes, it would be best to designate it as the "physiologic retraction ring," because the ring of Bandl was based on the frozen section of Braune, which was due to mechanical dystocia.

2. *Abnormal.*—(a) "The pathologic retraction ring" is the result of mechanical dystocia and an exaggera-

exit from the metaphysis near the epiphyseal disk where the cortex is paper thin. This teaching is extremely important in view of the fact that older textbooks state that the infection usually spreads directly into the medullary cavity of the main shaft. The infection may spread either directly or by way of the blood stream into the haversian canals and medullary cavity or it may pass directly through the epiphysis into the neighboring joint. Spread of the infection to the joint may also result from dissection of the capsule or articular cartilage (fig. 3). If the abscess perforates the metaphyseal cortex into the subperiosteal space, further spread of infection is largely determined by the relationship of the metaphysis to the attachment of joint capsule and periosteum (fig. 2). Most metaphyses are extracapsular and therefore the spread of infection is subperiosteal along the diaphysis or shaft. The periosteum may be stripped from epiphyseal disk to epiphyseal disk, so that the entire shaft may be infected by way of numerous periosteal vessels through the haversian system. Multiple small areas of bone necrosis may develop and this accounts for the "spotty" appearance of radiographic studies of chronic osteomyelitis. The proximal femoral metaphysis is of special interest, since it is completely intracapsular. Perforation of its cortex, as previously explained, invariably involves the hip joint.

The abscess may dissect the periosteum varying distances along the shaft and rupture through the periosteum into intermuscular planes and subcutaneous tissue and finally point beneath the integument. The subcutaneous abscess may be over the middle of the shaft of the bone, but the source of the abscess is the affected metaphysis.

#### TREATMENT

The treatment of acute hematogenous osteomyelitis includes a conservative surgical program following the principles laid down by Starr. Adequate attention to the general state and dehydration of the patient are also primary considerations. Children with acute hematogenous osteomyelitis should be divided into two groups. The division depends on whether or not the abscess has perforated the cortex of the infected metaphysis. In the first group the infection is confined within the metaphysis and the infection has not penetrated its thin wall or cortex. Therefore a subperiosteal abscess will not be encountered at the time of surgical exposure of the metaphysis. This phase is present during the first twenty-four, thirty-six or forty-eight hours of the clinical manifestations of the disease. It is this phase which I have described as acute hematogenous metaphysitis when diagnosis is rarely made and surgical drainage more rarely provided. The infection has not yet spread beyond the metaphysis, and adequate surgical treatment may prevent extensive involvement of the main shaft with necrosis and sequestration of bone. It is during this phase that the physician has an opportunity to influence appreciably the prognosis as to both mortality and morbidity.

Through a small incision the surgeon exposes the affected metaphysis and not the main shaft. The incision should be made directly over that portion of the metaphysis which was extremely tender. The cortex of the metaphysis is exposed subperiosteally. The periosteum should not be elevated except in the region of the metaphysis which is to be decompressed. Several drill holes are then made directly into the cancellous bone of the metaphysis, or a window about a half-inch by 1 inch is removed from the metaphyseal cortex in the

juxta-epiphyseal region. The cancellous bone of the metaphysis should not be curetted. If pus is encountered, a specimen should be sent to the laboratory for bacterial cultures. If pus is not found, a culture should be taken of a small portion of the cancellous bone. The wound is lightly packed with petrolatum gauze according to the Orr method and then covered with sterile dressings and sheet wadding. A plaster-of-paris cast is properly applied for the dual purpose of physiologic rest and the prevention of deformity of the affected extremity.

As the metaphyseal abscess develops it will drain through the surgical openings or window into the overlying dressings instead of taking a subperiosteal course with spread of the infection to the main shaft and medullary cavity.

One should not anticipate a dramatic ending of the clinical signs and symptoms of the acute infection following operation. The bone involvement is only a localized manifestation of a general blood stream infection. The clinical course will usually continue as a severe general infection until the defensive mechanisms of the body begin to gain control. Continuation of the signs of a general infection postoperatively should not be interpreted as spread of the skeletal infection if the original surgical drainage was properly performed. However, the extremity should be vigilantly observed for swelling, redness, edema, pain and tenderness, which are clinical manifestations of spread of infection. During this critical period the patient needs rest and fluids in order to combat the problem of dehydration. Other bone lesions may develop subsequent to the primary one. They cause less acute reactions; however, they should be dealt with in the same manner as the original bone focus.

Although the clinical course of the acute infection is not appreciably shortened by this program of therapy, there is no doubt that the skeletal involvement and morbidity are greatly reduced.

In the second stage of the acute phase of hematogenous osteomyelitis the infection has perforated the cortex of the metaphysis and spread subperiosteally along the shaft of the affected bone or directly within the neighboring joint. There is a definite change in the clinical manifestations after the metaphyseal abscess perforates the juxta-epiphyseal cortex. Pain and tenderness are no longer localized to the region of the primary bone focus in the metaphysis but extend over a greater area corresponding to the spread of infection. Swelling, redness and edema are now present. The contour of the extremity is no longer normal as it was before perforation. It is during this critical period that the disease is generally recognized and treated. The treatment is not only delayed but often is too radical. It is in this group of patients that dehydration is pronounced. The local bone and joint infection should not be considered the major issue until measures have been instituted to improve the general resistance of the patient and to restore body fluids. Generous quantities of physiologic solution of sodium chloride, 5 per cent dextrose, multiple blood transfusions and immune serum may be indicated.

A subcutaneous or subperiosteal abscess is present. The abscess may extend the entire length of the diaphysis. The bone is stripped of its periosteum and may appear "dead" although radiographic studies of the entire bone are negative for any evidence of infection.

It is certain that the abscess should be completely incised and drained. It is also just as certain that the

of the number of hours of labor, unless the labor is otherwise complicated. When the constriction ring relaxes, or rather the uterus begins to function normally, the normal physiology of the uterus effects a normal mechanism of labor (fig. 7).

#### DIAGNOSIS

In the presence of prolonged labor and in the absence of other causes of prolonged labor, my experience has caused me to make a speculative or an absolute diagnosis of a constriction dystocia. I consider the speculative diagnosis in all cases of prolonged labor. The absolute diagnosis can be made only by an intra-uterine examination and palpation of the constriction ring.

Fig. 3.—Early pregnant uterus of the Ungulata (cow).

This may account for the fact that I have observed or absolutely diagnosed only twenty-one cases of constriction ring dystocia.

My criterion for a constriction ring dystocia is a prolonged labor with a

normal cephalopelvic relation, position and presentation in either the first or the second stage of labor, other possibilities being ruled out. The diagnosis of cephalopelvic relation, position and presentation should be made during the antepartum supervision and confirmed as soon as possible after the onset of labor in order to be prepared to manage a mechanical dystocia.

The diagnosis consists in the evaluation of the following observations:

1. Labor is prolonged.
2. The uterine contractions vary in frequency, intensity and duration. The uterus may manifest tetany of the upper and the lower uterine segment, or tetany in the upper uterine segment and atonia in the lower uterine segment during the first or the second stage of labor. In such instances a speculative or an absolute diagnosis of constriction ring dystocia will prevent hasty intervention.
3. No change in the station of the presenting part, associated with a looseness of the fetal head in the pelvic cavity during the second stage of labor, has been pathognomonic in my experience.
4. There is laxity of the cervix during a uterine contraction. The laxity of the cervix and the lower pole of the uterus is very characteristic, and at times pathognomonic, of a complicating constriction ring dystocia. During a uterine contraction the external os does not contract or become tense as during a normal uterine contraction. When a constriction ring is manifested during a prolonged labor with a persisting cervical dilatation of from 7 to 8 cm. and when an intra-uterine examination is made, it is noted that the hand can be easily passed through the external os during a uterine

contraction. This phenomenon I have found present in all my cases during the first stage of labor.

During a uterine contraction, intra-uterine palpation demonstrates a flaccidity of the lower pole of the uterus, which coincides with the relative atonic stage of the cervix. When a constriction ring is located about the fetal neck, I have found the uterine wall from the constriction ring to the external os to be relatively atonic in either the first or the second stage of labor.

5. Exhaustion is frequently stressed as a complication of prolonged labor. I am firmly convinced that exhaustion is most often due to improper management of the parturient. If the parturient is properly managed, exhaustion will not be a factor of much account in either the morbidity or the mortality of the mother. I believe that puerperal sepsis and shock are much more likely to occur if the parturient patient is permitted to become exhausted by improper management.

#### PROGNOSIS

A review of the collected cases demonstrates the seriousness of a constriction ring dystocia. The maternal mortality of the 371 cases is fifty-four deaths, or 15 per cent. The causes of the deaths are given in table 2.

The fetal mortality of the 378 children is 172 deaths, or 46 per cent. In view of the operative difficulties of those who survived, one may speculate on the number of permanent disabilities.

In reviewing the 371 cases, it is noted that in 25 per cent of the cases intervention was done during the first stage of labor. It is also noted that in 154 cases, or 42 per cent, the primary obstetric procedure ended in failure and had to be terminated by some other

Fig. 4.—Late pregnant uterus of the Ungulata (cow).

obstetric procedure (table 3). A review of table 3 conclusively demonstrates the result of hasty intervention in both the first and the second stage of labor. I have no doubt that a proper evaluation of this obstetric complication, if managed by the conservative method, would have markedly decreased the maternal and fetal mortality.

In the 371 cases reported, operative procedures were resorted to in 97 per cent. A statistical study of the

the central nervous system. This has been termed the central effect in distinction to the peripheral sympathomimetic action. The exact site of this action is not at present clearly understood. Ephedrine shows this effect in that moderate doses may be followed by nervousness, tremor, nausea, sweating and insomnia. Experimentally it was shown as early as 1913<sup>3</sup> that narcotized animals may be awakened by ephedrine, and this drug has been

The chemical structure of epinephrine, ephedrine and beta-aminopropylbenzene (benzedrine).

used in patients as an antidote for narcotic drugs.<sup>4</sup> Schmidt<sup>5</sup> has demonstrated a stimulation of the respiratory center. The central action of ephedrine results in unpleasant side effects when the peripheral response is desirable. The central stimulating action has been utilized therapeutically in the treatment of narcolepsy and good results have been reported.<sup>6</sup>

Alles<sup>7</sup> noted that beta-aminopropylbenzene possessed a powerful central action with a comparatively weak peripheral effect. Prinzmetal and Bloomberg<sup>8</sup> found that beta-aminopropylbenzene was approximately three times as effective in narcolepsy as ephedrine. Their observations have been confirmed more recently.<sup>9</sup> In two patients suffering from typical narcolepsy, treated over a period of four months, I have observed similar remarkable therapeutic results. Typical narcolepsy is encountered infrequently, but symptoms of a milder degree simulating those of narcolepsy are commonly observed. The two chief features of narcolepsy are (1) attacks of somnolence and (2) paroxysms of extreme weakness and helplessness (cataplexy). The true nature of a narcolepsy is uncertain, but it has been suggested that this condition merely represents an exaggerated state of drowsiness and exhaustion, complaints that are encountered daily by the physician. Daniels<sup>10</sup> in his discussion of the nature of narcolepsy suggests that "the symptoms of narcolepsy represent little more than gross exaggerations of normal weaknesses of the flesh. Diurnal drowsiness is obviously a common failing and many of us are aware of relaxation of certain parts or experience difficulty in bringing certain muscles into play under conditions of emotional stress."

The effectiveness of beta-aminopropylbenzene in narcolepsy suggested a trial of the drug in patients who complained of exhaustion and who tired easily. Beta-

aminopropylbenzene sulfate was administered to forty such patients. Most of these patients did not suffer from organic disease and could be included under the diagnosis of nervous exhaustion. Focal infection was present in some instances and in other cases the exhaustion followed an infection. The drug was administered in tablets containing 10 mg. Most of the patients received a daily dose of 20 mg., one tablet before breakfast and another before the noon meal. In patients in whom fatigue was most evident late in the day, a single dose of 10 or 20 mg. was given about 11 o'clock in the morning. The drug was used for periods varying from a week to three months. With but few exceptions, a rather striking physical and mental reaction was noted.

#### EFFECT ON FATIGUE

In approximately 80 per cent of the patients there was a marked amelioration of this symptom. Many of the patients had complained of fatigue for long periods and had tried various types of treatment without benefit. In four instances the state of exhaustion was associated with a low metabolic rate. Although thyroid extract had been used with little effect, each of these patients stated that the sense of general fatigue and sluggishness was almost completely eliminated by the beta-aminopropylbenzene sulfate.

Four patients complained of migraine attacks when they became especially tired. Amelioration of the fatigue by beta-aminopropylbenzene sulfate appeared definitely to lessen the frequency of the migraine attacks. In one patient, an interval of dizziness constantly preceded the onset of the migraine. She has been able to prevent the headaches repeatedly by taking one tablet of beta-aminopropylbenzene sulfate in the prodromal stage.

#### MENTAL EFFECTS

A sense of increased energy and capacity for work was noted in more than half of the cases. In addition, a feeling of exhilaration and sense of well being was a consistent effect. This followed repeatedly after the ingestion of the drug. In a few patients there was a secondary depression following the initial stimulation. Many patients volunteered that there had been a definite increase in mental activity and efficiency. Another striking reaction was a tendency to loquaciousness. This was very marked in many instances and was noted both by the patients and by those about them.

#### EFFECT ON WEIGHT

Ten patients noticed a marked loss of appetite and with this a definite reduction in weight. Two patients stated that they had lost their craving for sweets. The loss of weight varied from 7 to 20 pounds (3.2 to 9 Kg.). The most marked loss in weight occurred in a patient with narcolepsy who lost 20 pounds in a period of two months. After the initial loss, in each instance the weight remained stationary with the continued use of the drug. A study of the basal metabolism in two patients who had lost weight indicated that the loss of weight was not due to an increase in the basal metabolic rate. The loss of weight can probably be explained by the lessened appetite and increased physical activity.

#### UNPLEASANT REACTIONS

Unpleasant effects were observed by a relatively small number of patients. Dryness of the mouth, disturbed sleep, transitory tremor of the hands, sweating and palpitation were noted. The unfavorable reactions were

sistency 5 or 6 cm. above the external os and the presenting part above the ring, which was behind the symphysis pubis. There was no vaginal bleeding. The membranes were intact.

At 9 p. m. rectal examination showed that the presenting part was floating. Ten minims of epinephrine was given, followed in one hour by morphine and scopolamine. The routine medical regimen was given for exhaustion.

March 18, at 4 a. m., there was spontaneous delivery of an eight months' living child.

The postpartum course was normal and the mother and child were discharged on the tenth postpartum day.

#### TREATMENT

The management of constriction ring dystocia is that of a prolonged labor. The basic principle is to maintain the parturient patient's mental and physical condition in order to prevent exhaustion as a complication in the first stage and to permit art to assist the parturient in the second stage, if necessary.

*The First Stage of Labor.*—The treatment may be termed "intelligent expectancy" (De Lee). The labor is considered to be prolonged at eighteen hours after the onset of labor when the state of the cervix gives one the impression that the first stage will be prolonged; the state of exhaustion must be anticipated and the treatment instituted to prevent exhaustion.

*The Medical Regimen for Exhaustion.*—At the end of eighteen hours the urine is tested for acetone, the test being repeated every twelve hours. The diet, soft or liquid, should consist of 3,000 calories of food rich in carbohydrates, and 2,000 cc. of water for each twenty-four hours of the labor. The patient should be fed every three or four hours. With persuasion she will cooperate. She should receive sufficient sedatives to ensure adequate rest or sleep. This management will prevent exhaustion as a complication of a prolonged labor. A negative acetone test throughout a prolonged labor should be the criterion for the proper management.

The parturient is conservatively managed until the second stage is reached, which may require from twenty-four to 100 hours. However, one must be continuously alert and diagnose any complication that may endanger the mother or child. The complication determines the indication for change in management.

A review of reported cases shows that in eighty-one, or 25 per cent, intervention was done during the first stage, with a maternal mortality of ten, or 13 per cent, and a fetal mortality of forty-four, or 56 per cent. These figures speak against operative intervention in the first stage. Dührssen's incision is condemned in this complication, as it is the constriction ring and not the cervix that is obstructing the descent of the fetus.

*The Second Stage of Labor.*—When the second stage is complicated by a constriction ring, intervention should not be gaged by the number of hours but rather on the condition of the parturient or the fetus for the indication.<sup>24</sup> There is no evidence showing that the uterus will rupture spontaneously, irrespective of the number of hours in labor.

When to resort to operative intervention in prolonged labor depends on the conditions governing the indication rather than on the time element of the second stage. When the functional dystocia in the second stage is manifested by inertia uteri, operative intervention at the end of two or more hours yields excellent results; but when a constriction ring dystocia is diagnosed, operative intervention must be very carefully weighed before proceeding.

The conservative management of a constriction ring dystocia will be illustrated by citing two cases, in which a speculative diagnosis was made during the first stage and an absolute diagnosis was made during the second stage. In the first case, after two hours in the second stage a trial of delivery with the forceps was made, but when too much resistance was encountered the forceps was removed. An intra-uterine examination disclosed a constriction ring around the fetal neck from 7 to 8 cm. above the external os. The patient was given morphine and scopolamine, as indicated, and after twenty-four hours in the second stage a spontaneous delivery of a living child was obtained with no morbidity to the mother during her postpartum period. In the second case an absolute diagnosis was made after two hours in the second stage. Morphine and scopolamine were given as indicated. At the end of eighteen hours the fetal head had descended from plus one to plus three, where it remained for one hour. Then the labor was easily terminated by low forceps with a living child and no maternal morbidity.

If the constriction ring does not relax on waiting or on giving morphine and scopolamine, other pharmacologic agents are resorted to.

Anesthesia is a fundamental requirement in all operative procedures and should give the greatest degree of relaxation of the constriction ring. The usual anesthetic agent is ether, although I prefer chloroform if it can be properly and safely administered. It should be administered to the point of deep surgical anesthesia and at times fairly well prolonged in order to secure the maximal effect on the constriction ring. Ethylene, nitrous oxide and oxygen from my experience do not appear to be favorable for the relaxation of the constriction ring. Atropine and cocaine have been used with no success. Amyl nitrite has been used with some success. The value of epinephrine, as advocated by Rucker,<sup>25</sup> has been demonstrated. Rudolph and Ivy,<sup>1</sup> and Ivy, Hartman and Koff<sup>6</sup> demonstrated that it would even diminish uterine activity initiated with solution of posterior pituitary. I have had some excellent results by its use and some failures. My routine procedure with epinephrine is as follows: Before the subcutaneous injection of epinephrine, the hand is introduced into the uterus, so that the dorsal aspect of some of the fingers is in contact with some portion of the constriction ring. Ten minims of epinephrine is injected. I wait a few minutes to determine the effect on the constriction ring. If no relaxation is evident, I give another injection of 5 minims (0.3 cc.) and wait fully five minutes. If at the end of five or ten minutes I find no evidence of relaxation of the constriction ring, the anesthesia is stopped and the parturient patient is treated by the conservative management. If evidence of relaxation of the constriction ring is obtained, delivery is accomplished either with the forceps or by version and extraction, preferably by forceps.<sup>2</sup>

#### CONCLUSIONS

1. Intra-uterine rings frequently complicate prolonged labors.
2. The intra-uterine rings are found at different uterine levels, so that the designation of contraction of the ring of Bandl, contraction ring dystocia and retraction ring dystocia is not tenable.
3. Constriction ring dystocia is suggested for this complication on biologic grounds.

24. Rudolph, Louis: *Am. J. Obst. & Gynec.* 25: 840 (June) 1933.

25. Rucker, M. P.: *Am. J. Obst. & Gynec.* 14: 609 (Nov.) 1927.

the action, but the usual report was that the reaction lasted until the early or latter part of the evening, a period varying from seven to twelve hours.

#### REACTIONS OF CONTROL GROUP

The reactions of the twenty-five subjects who received the lactose tablets were remarkably consistent. Twenty-one, or 84 per cent, reported no reaction of any type. Two subjects stated that they were aware of slightly increased fatigue and one described a fluttery feeling, transient and mild, shortly after the ingestion of the tablets. In one questionnaire, increased energy, lessened fatigue, increased talkativeness and euphoria were indicated as being present in a mild degree, designated as one plus. When the responses of the two groups were compared, it was evident that the questionnaire method was highly reliable for the study of the subjective effects of the drug.

#### COMMENT

The results of this study indicate that beta-aminopropylbenzene (benzedrine) exerts a definite stimulating effect on the higher centers of the central nervous system in most individuals. There is a great variation in the intensity of the response, but in most instances the administration of the drug is followed by a marked lessening of fatigue, an increase in mental and physical activity, and a distinct feeling of exhilaration.

The reactions observed indicate that the drug may have a rather wide therapeutic application but a more prolonged experience is required to determine the exact indications. In patients who become easily fatigued or who are in a chronic state of exhaustion, the drug seems to exert its most favorable effect. This treatment is, of course, symptomatic and should be used only when all physical causes of fatigue have been considered and eliminated. The drug would seem to have its greatest value in the most frequent type of fatigue, that of nervous exhaustion. The symptomatic relief in patients of this type appears to have a decidedly beneficial effect. A limited experience in four patients suffering from mental depression indicates that this condition may also be favorably influenced. From observations in a group of normal individuals, it would appear that a very important purpose which may be served by the drug is the preparation of an individual for situations that require the expenditure of unusual amounts of physical or mental energy.

It is obviously of importance to consider the question of possible harmful effects, including the possibility of habituation and development of a tolerance. A wider and longer experience with the drug is necessary before this question can be definitely settled. The indications from several sources, however, are that the substance is without harm even on prolonged use. This evidence is derived from (1) pharmacologic studies on beta-aminopropylbenzene, (2) clinical observations on the closely related compound ephedrine, and (3) clinical studies with beta-aminopropylbenzene, although the observations have as yet been comparatively limited.

Pharmacologic studies indicate that beta-aminopropylbenzene is of remarkably low toxicity. The minimum lethal dose for the rat is 25 mg. per kilogram of weight, and for the guinea-pig 34 mg. per kilogram of weight.<sup>11</sup> The low toxicity is apparent when one considers that a dose of from 10 to 20 mg. has a definite

effect in most individuals. Investigators agree that the prolonged use of ephedrine, a compound closely related to beta-aminopropylbenzene, does not have any cumulative harmful effects and does not result in habit formation.<sup>4</sup> It will require further investigation to determine whether this applies fully to beta-aminopropylbenzene. Although experience with prolonged use of this substance has been limited, the results up to the present indicate that there are few, if any, harmful effects. One patient, reported by Prinzmetal and Bloomberg, received the drug for fourteen months; no harmful effects are mentioned and the original daily dose of 20 mg. continued to be fully effective. I have observed four patients who have received daily doses of from 20 to 40 mg. for a period of four months. The initial dosage was still effective and, except for a moderate loss of weight, there were no effects that might be considered harmful.

It is well known that drugs of the epinephrine series raise arterial pressure in certain dosage. No such effect was noted in the present studies with beta-aminopropylbenzene. It is apparent that the peripheral effect requires a definitely larger dose than that which produces a central action. This is very desirable, since a sympathomimetic effect over a long period might be distinctly harmful. Epinephrine and ephedrine will induce cardiac irregularities in many individuals, and this increased cardiac excitability is especially dangerous in patients suffering from coronary disease. The development of extrasystoles apparently due to the beta-aminopropylbenzene was observed in only one instance. In four patients who showed ventricular extrasystoles, this drug did not seem to increase the frequency of the ectopic beats.

A definite possibility of a harmful effect exists in that prolonged administration may result in an increased activity and energy expenditure beyond the capacity of some individuals. This is particularly likely since the protective and retarding influence of fatigue is lost.

The judicious administration of the drug should effectively prevent such a harmful action, but it is conceivable that this may occur in patients who are taking the drug without the guidance of a physician.

#### CONCLUSIONS

1. Beta-aminopropylbenzene (benzedrine) produces in most individuals a definite stimulation of the central nervous system in doses which do not result in a peripheral sympathomimetic action.

2. Euphoria, a feeling of exhilaration, lessening of fatigue, an increased energy and capacity for work and talkativeness follow quite regularly the administration of from 10 to 20 mg. of beta-aminopropylbenzene sulfate.

3. Although the drug has its most striking effect in narcolepsy, it acts favorably in states of persistent exhaustion and in individuals who become easily fatigued. The reactions observed indicate that patients who are in a depressed state may be benefited.

4. Studies in normal individuals indicate that benzedrine increases energy and efficiency to a degree that the drug should be of value in the preparation of individuals for activities that require an unusual expenditure of physical and mental energy.

5. The complete indications and contraindications in the use of the drug must await the results of further experience.

which in the majority of instances is a temporary state. When a prolonged labor is mismanaged by lack of food, water and rest or sleep, increased catabolism of the skeletal musculature with excessive formation of lactic acid takes place. The acidosis present is due to improper management of the parturient, and the uterus per se plays a very minor rôle in the process. Exhaustion during labor must be anticipated and prevented by the medical regimen that I have outlined.

## TULAREMIA

REPORT OF A FULMINANT EPIDEMIC TRANSMITTED  
BY THE DEER FLY

CHARLES C. HILLMAN, M.D.

AND

MARK T. MORGAN, M.D.

Lieutenant Colonel and Captain, Respectively, Medical Corps, U. S. Army  
SAN FRANCISCO

Tularemia is a disease that does not usually occur in epidemic form. Ordinarily one sees only sporadic cases or at most only a very few cases infected from the same source. But with conditions sufficiently favorable it is a disease that may assume epidemic proportions. This study concerns such a situation, which arose in a Civilian Conservation Corps camp in northern Utah during the summer of 1935.

The history shows that this camp consisted of about 170 enrollees located on the treeless plains north of Great Salt Lake. The men were engaged largely in road construction, and because of the excessive heat many of them worked without shirts or other covering above the waist. July 11 one of the enrollees appeared on sick report with fever, headache, general malaise and enlarged tender lymph nodes in the right supraclavicular area. Approximately twenty-four hours later a punched-out, sloughing ulcer about 1 cm. in diameter developed in the posterior cervical region. A few similar cases appeared during the next ten days, the only variation being in the location of the ulcers, on the neck, shoulders, back, arms or face and in the involvement of the corresponding regional lymph nodes. The cases gradually increased in number until during the eight day period, from July 23 to 30, there were seventeen admissions for the disease. On the latter date movement of the camp to a more favorable location was begun, after which only two additional cases appeared. During the acute stage the patients were hospitalized in local hospitals in Brigham City and Tremonton. It is of interest to note that this is the same Brigham City from which Dr. R. A. Pearse made the first report of human cases of tularemia in a paper read before the Utah State Medical Society in 1910. Following the acute phase of the disease the patients, thirty in all, were assembled and transferred in one group to Letterman General Hospital for further observation and hospital care. After detailed laboratory studies and several weeks of clinical observation, final diagnoses of tularemia were made in twenty-six cases. Another CCC enrollee was in the hospital at the time with tularemia. He had acquired the disease at a camp in Mississippi just before the transfer of his company to California. A young woman, now under observation, apparently acquired the disease a few months ago during a short winter vacation in a tourist camp in the

Sierra Nevada Mountains. The last two cases showed primary lesions near the knee with inguinal adenitis. The offending insects were not identified. Although a total of twenty-eight cases form the basis of this study, the epidemic feature applies only to the disease as it occurred in the Civilian Conservation Corps camp in northern Utah.

Study of these twenty-eight cases showed twenty-seven to be of the ulceroglandular type. One that showed no primary lesion was classified as glandular.

The location of the primary lesions proved to be very interesting. In the ulceroglandular type of tularemia the ulcer usually occurs on the finger or hand where infection occurs through contact with an infected rabbit or other infected material. In this group none had primary lesions on the fingers or hands and only one a lesion on the arm below the elbow. Two patients each had two primary ulcers. A few had one or more secondary lesions appearing near the main primary, apparently caused by killing the offending insect or spreading the infection by scratching soon after the bite. Of the twenty-nine primary lesions, twelve were located on the back, six on the shoulders, five on the arms, three on the legs, two on the neck and one on the chin. The unusual preponderance of initial ulcers on the back and shoulders is explained by the enrollees' habit of working without shirts.

In most cases the primary ulcer appeared from twenty-four to forty-eight hours after the onset of the illness, but in some the ulcer, fever, general malaise and regional lymphadenitis developed simultaneously. The pain and tenderness involved the glands, the periglandular tissues and the intervening regions between the primary lesions and the lymph glands to which they drained.

Their temperature charts showed rather similar curves, usually a high initial rise, above 104 F. in some cases, followed by remissions and less marked secondary and tertiary elevations. The temperature usually remained normal after the third week, though several still showed febrile periods above 102 F. as late as the sixth week. Our most recent case is still in the hospital presenting elevations of temperature of one degree three months after onset.

The patient with no primary lesion had right axillary nonsuppurative adenitis. In one with the inoculation on the leg inguinal and later axillary adenitis developed, all on the same side of the body. Both groups of glands in the latter case eventually broke down and required incision. All other cases showed regional lymphadenitis but in no case was there general glandular involvement. Sometimes two groups of glands showed reactions to a single primary lesion; i. e., the axillary and supraclavicular to a single ulcer on the shoulder. The glands varied in size from that of an almond to that of a small orange. Some of them remained tender and eventually suppurated as late as four months after the onset of the disease. Sixteen of the twenty-eight cases required incision of one or more glands.

Treatment consisted largely of rest, generous feeding, surgical drainage of suppurating glands and general ward care. Five cases were treated with Foshay's serum, 12.5 cc. intravenously on two successive days. Five other cases were treated with 1 per cent mercurochrome in 7.5 per cent dextrose solution intravenously, 5 cc. gradually increased to 10 cc. every other day for five doses, the course being repeated after an interval of ten days. These patients received their serum or mercurochrome during the sixth to the eighth week.

From the Letterman General Hospital.  
The authors are indebted to Dr. Karl F. Meyer, director of the Hooper Foundation for Medical Research of the University of California. He placed the facilities of the foundation at their disposal, contributed freely of his own time in seeing the patients and offered many valuable suggestions in carrying out the study.

tion of the "physiologic retraction ring," which is analogous to the ring of Bandl. This term is preferable because it connotes the physiologic changes in mismanaged cases of mechanical dystocia.

(b) The constriction ring is an annular contraction of the uterus which may occur at any level of the uterus and causes dystocia per se in the presence of normal cephalopelvic relation and position and presentation.

Fig. 1.—Pregnant uterus of the dog (uterus bicornis unicollis).

#### TYPES OF CONSTRICTION RINGS

On the basis of clinical experience and physiologic knowledge, two types of constriction rings may and do occur:

1. A spasmodic reversible constriction ring, which relaxes under the influence of anesthesia or incision, as is frequently observed when cesarean section is performed on these patients or after morphine and rest, after epinephrine or after death.

2. A permanent nonreversible constriction ring, which does not relax under anesthesia or drugs, or even after death, as in the cases reported by White,<sup>19</sup> Phillips,<sup>20</sup> Hannah and Massey,<sup>21</sup> Carson<sup>22</sup> and Michael.<sup>23</sup>

#### ETIOLOGY

A study of the 371 cases relative to age, parity, rupture of the membranes or bags, malposition and malpresentation, and drugs does not present any evidence that these factors played a rôle in the obstetric complication. Intra-uterine manipulations were studied. From the 318 cases reviewed, the stage of labor at which intervention was instituted was first stage in eighty-one, or 25 per cent; second stage in 237, or 75 per cent. It is noted that 25 per cent were interfered with during the first stage for indication to deliver on account of either the mother or the child. After studying these cases it would appear to me that the constriction ring dystocia was present in every instance before the intra-uterine examination.

#### PATHOLOGY

Annular uterine rings are spasmodic and permanent. The spasmodic rings, on account of their temporary nature, cannot be studied histologically. Through the courtesy of White,<sup>19</sup> Phillips<sup>20</sup> and Hannah and Massey,<sup>21</sup> who have sent me a portion of their specimens, I have been able to study these rings, which I will discuss briefly.

The histologic examination demonstrates that the transverse muscle fibers are markedly more numerous and thicker than those found in the control sections. The longitudinal muscle fibers are definitely less numerous and show only a moderate degree of tortuosity; they are not as short and thick as those found in the control sections. These histologic changes are in keeping with the physiologic changes. That a permanent constriction ring is not due to spasm is indicated by the fact that it persisted after death or hysterectomy.

#### MECHANISM OF LABOR

When the constriction ring is in spasm, the movements of the passenger are arrested. The ring causes an incoordination of the uterus in which no change takes place in either the upper or the lower uterine segments. The constriction ring does not rise irrespective of the duration of labor but maintains a stationary position. The more essential points relating to the mechanism of labor, when the ring complicates the first or the second stage of labor, is as follows:

*The First Stage.*—The fetal head may be in an attitude of either flexion or deflexion. Since the movement of descent does not occur during the normal first stage of labor (descent during the first stage is due to the elongation of the lower uterine segment), the station of the fetal head has not the same significance as in the second stage. With a normal cephalopelvic relation the fetal head will be found loose in the pelvic cavity, because the uterine dysfunction caused by the constriction ring prevents the presenting part from coming into firm contact with the lower pole of the uterus for the normal mechanism of labor. Dilatation of the cervix may take place during the first stage of labor at a very slow rate, which is explained on the basis of intermittent relaxation of the constriction ring permitting coordination of the uterus for intermittent uterine changes (fig. 6).

Fig. 2.—Pregnant uterus of the rabbit (uterus didelphys).

*The Second Stage.*—When the constriction ring persists or occurs after complete dilatation of the cervix, the effectiveness of the uterine contractions in causing the important movement of descent is arrested. Of course, the movement of internal rotation does not occur because of the incoordination of the uterus. As previously indicated, the uterus will not spontaneously rupture during the second stage of labor, irrespective

acquired the disease while enjoying winter sports in the Sierras late in January is not so clear. She became ill the day of her homecoming, developed a typical ulcer on the lateral surface of the right knee with a right inguinal bubo the size of an egg, and had an intermittent fever lasting three months with elevations above 104 F. during the early weeks. Her blood serum shows a strong agglutination of *B. tularensis* in a dilution of 1 to 640. She occasionally eats rabbit flesh, prepared and cooked by a maid. But she had consumed no rabbit flesh for some weeks prior to the onset of her illness. It appears likely that she acquired the disease through the bite of a bedbug or tick in her winter cabin in the Sierras.

## COMMENT

1. The experience recorded shows that under favorable conditions tularemia may assume epidemic proportions.

2. Unless proper precautions are taken, the success of military operations and construction projects in highly infected regions may be jeopardized.

3. Danger of acquiring the disease through contact with the pus from suppurating glands is negligible.

4. Skin sensitivity tests with *B. tularensis* antigen proved to be a valuable diagnostic procedure.

5. Even during the winter months, insect transmission of the infection appears to be possible.

THE INJECTION TREATMENT  
OF HERNIA

NATHAN N. CROHN, M.D.  
CHICAGO

Critical evaluation at this time of the injection method of treating hernia is highly desirable. It is my belief at present that by this means permanent cure can be effected, but only in suitable, selected cases.

The physician is under strong pressure from many sources to employ this form of treatment. Syndicated newspaper articles<sup>1</sup> have appeared instructing the public that the treatment is established, that the physician who does not employ it is backward, and that it is opposed by the orthodox profession because it is new and hence unorthodox. The patient of course seeks to avoid an operation, is ready to refuse surgical advice and is eager to pay much money for any promise of other cure. To illustrate the attitude of the public and not otherwise to be compared, a concern in St. Louis, recently debarred from the mails,<sup>2</sup> had gross receipts up to \$250,000 a year and many testimonials for a rupture cure that was essentially a piece of adhesive plaster and a little ointment to be applied on the skin. The physician for many reasons is impelled to wish for such a nonoperative treatment. A cynical and false one was mentioned by Dr. Carroll,<sup>3</sup> who, in discussing fads before the New York State Medical Society in 1889, said "Just as a man always comes when circumstances arise that demand his services, so fads come when it is necessary for the young practitioner to increase his income."

Pharmaceutical houses, by advertisements in journals, in the mail, and through detail men quote almost

100 per cent cures with the injection treatment, if their formulas are used, with a simple, bloodless, painless, easily learned procedure requiring only a few short office visits, practically no equipment, which does not interfere with the patient's work, eliminates hospital and disability expenses and generally has all the advantages and none of the disadvantages of open operation.

Today, as earlier, reprints of some of the published articles are included in the advertising matter or are referred to as supportive evidence of the scientific status of the treatment and of the solution. Only the trade name of the solution may be mentioned by the author of the article, and the formula even kept secret.<sup>4</sup> Many of the solutions are irrationally complex, if not of uncertain composition.<sup>5</sup>

Historical accounts are included in practically all articles written on the injection treatment of hernia. As a legitimate function, such a historical background serves first to provide a proper approach to the subject under consideration. It may also be of value to lend the weight of authority, of numbers of authors, and of otherwise notable, reputable names of men who have written about the treatment. Such names serve as "character witnesses" for respectability and frequently are included indubitably to influence the reader favorably. On the other hand, historical accounts and bibliographic references as first given by Mayer<sup>6</sup> may be erroneous and misleading, although not necessarily intentionally. Subsequent articles, even in the better journals, indicate simple repetition of references with undue elaboration. For example, Manley<sup>7</sup> who in his book on hernia most conservatively discusses the injection method, becomes one who made further contributions.<sup>8</sup> Marcy,<sup>9</sup> who two years before Manley dealt with the subject in a superior classic monograph on hernia, is referred to but rarely. The frequent mention of Manley by so many writers is apparently due to the reference by Mayer. In the same manner apparently Ripley,<sup>10</sup> who does not even mention the injection method, becomes an author on the subject.<sup>11</sup> Similarly Janney, although quoted by Warren<sup>12</sup> and Mayer, never actually wrote but is frequently referred to as an author.<sup>13</sup>

Velpeau<sup>13</sup> of Paris is mentioned in all such articles as the first to introduce the method in 1837 and, therefore, presumably recommended the treatment. As a matter of fact, Velpeau attempted the procedure in all a total of three times, specifically reported it as only experimental, and immediately abandoned it as a method of cure. Similarly, while it is true that Pancoast,<sup>14</sup> professor of surgery at Jefferson Medical College,

different operative procedures gives valuable information of the danger of hasty intervention in constriction ring dystocia (table 4). The figures speak for caution in hasty operative intervention.

The recent increase in the performance of cesarean section in general necessitates a careful analysis of the indication of this procedure in this complication. Cesarean section, therefore, based on the speculative diagnosis of a constriction ring dystocia complicating a prolonged labor, would increase the incidence of cesarean section with the high maternal and fetal mortality that recent investigation has disclosed. A study of the statistics demonstrates that cesarean section per se is not the answer for the management of constriction ring dystocia, because in 75 per cent apparently diagnosis was made and intervention done in the second stage of labor when conditions were not favorable. I have not performed a cesarean section in the presence of either a speculative or an absolute diagnosis.

Version and extraction were performed in 142, or 38 per cent, of the reported cases. The results demonstrate the seriousness of this procedure. I have performed two successful versions and extractions in constriction ring dystocia and one in which the patient died from shock. On evaluating the literature and my own experience, and being successful with less radical procedures, I have not employed this procedure since.

I would resort to this procedure only under very exceptional circumstances.

Forceps delivery was the method of choice in 137 cases, or 37 per cent. The results demonstrate the care necessary in evaluating the conditions present, for besides the mortality (table 4) and the failed forceps cases (table 3), a review of the literature on "failed forceps" and my own "failed forceps" cases may explain the cause of my failure.

In the light of my experience I believe that the prognosis for the mother and child can be markedly improved by a conservative management of a prolonged labor complicated by a constriction ring. In some cases failed forceps or contemplated cesarean section was followed by a spontaneous delivery or an easy low forceps operation. I have managed patients with prolonged labor on a speculative diagnosis with gratifying results, which is my practice today. I believe that with a conservative management the maternal mortality should be less than 2 per cent and a fetal mortality of not more than 15 per cent for constriction ring dystocia.

My experience consists of twenty-one cases (ten other cases since the foregoing statistics were compiled) in which an absolute diagnosis of constriction ring dystocia was made during the first and the second stage of labor. The following cases are typical in my experience:

CASE 1.—W. J., a primipara, aged 20, a Negress, whose history was of no importance, had her last menstrual period Nov. 20, 1934, and expected labor Aug. 27, 1935. She entered the Cook County Hospital Sept. 4, 1935, with the onset of labor at 12 a. m.

On examination at 3 a. m. the general condition was good. The cervix was partially effaced and the canal admitted a finger. Station was zero. Uterine contractions were irregular. The fetus was in the right occiput anterior position. Fetal heart tones were 140.

At 2 p. m. cervical dilatation was from 6 to 7 cm. Station was zero. Fetal heart tones were 140 and of good quality. There were uterine contractions every five minutes.

Failure in a primary obstetric procedure in 154 instances, or 42 per cent.

September 6, at 7 a. m., cervical dilatation was from 6 to 7 cm. Station was at zero. Fetal heart tones were 140 and of good quality, with uterine contractions every five minutes. The medical regimen for exhaustion was instituted. The acetone test was negative.

September 7, at 7 a. m., the patient was showing the strain of the labor. A sterile vaginal examination was made: cervical dilatation was 8 cm. The station was plus one. The cervix was thick and loose during a uterine contraction. A large caput was present. Intra-uterine examination revealed a constriction ring around the fetal neck. The patient was given morphine and scopolamine, and intravenous dextrose.

At 7:57 p. m. 10 minims (0.6 cc.) of epinephrine was given subcutaneously. Within a few minutes the fetal head descended to plus three.

At 8:30 p. m. the fetal head began to crown. An episiotomy was followed by a spontaneous delivery of a colored male child weighing 7½ pounds (3,400 Gm.).

At 8:43 p. m. there was a spontaneous delivery of the placenta.

The mother and child were discharged from the hospital, September 16, after a normal postpartum course.

CASE 2.—M. S., a Negress, aged 27, a secundipara, whose history was of no importance, had her last menstrual period June 10, 1934, and expected labor March 17, 1935. She entered the Cook County Hospital March 16, 1935, with onset of labor March 15, at 10 a. m.

The general condition of the patient was good. The temperature was 98.6 F., the pulse 94, and the blood pressure 90

systolic, 50 diastolic. The uterus was at term. Fetal heart tones were 146 and of good quality. Cervical dilatation was 6 cm. and the membranes were intact. There was slight vaginal bleeding. The presenting part was floating. There was cephalic presentation.

March 17, at 9 a. m., cervical dilatation was 6 cm. There were irregular uterine contractions. The uterus was in tetany, so a mild premature separation of the placenta was suspected.

At 5:30 p. m. a sterile vaginal examination was made. Cervical dilatation was 8 cm. The cervix was relaxed. Intra-uterine examination showed a thick definite ring of firm con-

Absolute alcohol was the irritant employed, and he stated that vital danger was never present.

Mayer<sup>9</sup> reports that he has observed since 1899 more than 2,100 hernias with 98 per cent cures. Even the 2 per cent of his failures he cures by further injections. He has seen no recurrence of his treated cases for a period of years.

McDonald<sup>22</sup> baldly claims that all reducible hernias in "normally built cases" can be permanently cured and that all ages are amenable.

Pine Mestre<sup>5</sup> recently reported 15,000 cases in which injections were variously made over a period of twenty years with a 98 per cent cure. He states that he closes the inguinal canal in from ten to fifteen days in almost any reducible hernia. There is no mention of follow-up difficulties.

Hall<sup>23</sup> reported one failure, explained as due to lack of cooperation, in thirty-three hernias injected.

Jameson and Cantala,<sup>24</sup> although favorably impressed by Mayer's work, used the Pine Mestre technic and solution in sixty-four cases with daily injections for from twelve to fifteen treatments. Of four recurrences, two were later "relieved" by additional injections.

Gray<sup>25</sup> of England followed Mayer's technic and claimed a 75 per cent cure. He gives no statistical analysis.

Bratrud<sup>26</sup> of the University of Minnesota reported the treatment of 406 hernias in 387 patients. "A very small number of these have been only fitted with trusses because of their advanced age or feebleness. The recurrences are a little less than 4 per cent including indirect and direct inguinal, femoral and epigastric hernias." In only three cases in which there was extreme difficulty in holding the hernia reduced has he been unable to effect a complete closure.

Rice<sup>27</sup> has treated more than 600 cases at the Minneapolis General Hospital without complications. He mentions difficulties in follow up but knows of only two failures.

Larson<sup>28</sup> of the University of Minnesota concludes that injections are suitable for "umbilical, inguinal, femoral, and certain types of postoperative incisional herniae, making up in all at least 90 per cent of these cases which are seen. For the remaining 10 per cent of herniae, injections may be used to supplement surgical repair." He used the phenol, alcohol and thuja solution, averaging eight injections, and reported a 93.5 per cent cure in a total of 137 hernias, including direct and indirect hernias of all sizes occurring in all age groups. Practically the only complication, occurring in 10 per cent of the cases, was effusion into the hernial sac. The swelling subsides in three weeks but frequently necessitates aspiration. He concludes that no harm results from the injections should the method fail to cure.

Quillan<sup>29</sup> reports favorably on the treatment and cured five recurrent, two umbilical and twenty-three indirect inguinal hernias. His only complication was an edema of the scrotum.

Fowler<sup>30</sup> thinks that the claim of 98 per cent cure is reasonable. He has treated 700 cases in five years. He "naturally" assumes that, if patients do not return, their hernias are "gone and forgotten." He treats all types of hernias, using a solution of plant extracts containing tannic and gallic acid irritants of meager description but having its own trade name advertised to the profession. He describes eight cases treated; one patient (case 6) was "diabetic at the outset, but during treatment, weekly tests showed sugar in the urine diminished and disappearing, probably because of a general return of health with the removal of hernial drag."<sup>30</sup>

#### REPORTS OF EXPERIMENTS

Experimental work on this subject that has been reported is inconclusive. The research has successfully demonstrated that the injection of irritating fluids produces scar tissue, but no work has been done to prove that such scar tissue per se cures a hernia. Indeed, the surgeon who takes great care to close an incision by meticulous apposition of the tissue in order to have the least possible production of scar tissue believes that large scarred areas are particularly prone to post-operative incisional hernia.

Hall<sup>23</sup> reported experiments on animals in which he injected into the abdominal wall a solution of alcoholic tinctures of many plants having a tannic acid composition (Pine Mestre). On histologic examinations, he obtained a proliferation of connective tissue cells with large mononuclear phagocytes and foreign body giant cells as in a foreign body granuloma. He found "regeneration of striated muscle." Hall concluded from his experiments that there is a "formation of adhesions and a connective tissue barrier, thus effectively blocking and obliterating the canal." Wolfe,<sup>31</sup> using the same solution, produced an experimental plastic peritonitis in animals. He states that injection into and around the spermatic cord left the lumen patent, the epithelial lining intact, and perfect preservation of the vas deferens. Bratrud<sup>26</sup> used various solutions in dogs and rabbits and recommended one consisting of the distillate of the tinctures of several herbs, to which is added 0.1 per cent tannic acid and 0.5 per cent thymol. He reports that microscopic sections show a marked proliferation of fibroblasts, with no infiltration of polymorphonuclear cells, giant cells or necrosis. McKinney<sup>32</sup> used experimentally a solution consisting of 50 per cent phenol, 25 per cent alcohol and 25 per cent oil of thuja, and produced young fibrous connective tissue without necrosis, hemorrhage or leukocytic exudation. The fibroblasts penetrated adjoining muscles and appeared firmly attached to them. Rice,<sup>27</sup> also using the latter solution, reports that histologic examination of tissues obtained from patients at operation at various intervals after experimental injections indicated an early reaction consisting of exudation with polymorphonuclear and round cells, with evidence of cellular necrosis. Later, fibroblasts appeared and the polymorphonuclear cells disappeared. Dense adult fibrous tissue was present by the forty-second day.

4. The diagnosis is either speculative or absolute.  
5. The criterion of an absolute diagnosis consists of a prolonged labor, no change in the station of the presenting part in the second stage of labor, looseness of the fetal head in the pelvic cavity, relaxed cervix during a uterine contraction, and intra-uterine palpation of the constriction ring.

6. The majority of constriction rings are found behind the symphysis pubis and from about 6 to 8 cm. above the external os.

7. In a normal cephalopelvic relation, position and presentation delivery by the vagina is the safest for mother and child.

8. The management of a prolonged labor should consist in the prevention of maternal exhaustion by a sufficient intake of food, water and rest for each twenty-four hours of the labor. A negative acetone is the criterion of a well managed parturient.

9. The conservative management bespeaks no operative intervention until the constriction ring has relaxed, leaving out indications that may point to intervention for either mother or child.

10. A conservative management should result in a maternal mortality of less than 2 per cent and a fetal mortality of less than 15 per cent.<sup>26</sup>

55 East Washington Street.

#### ABSTRACT OF DISCUSSION

DR. M. P. RUCKER, Richmond, Va.: I am in hearty agreement with the author as to the diagnosis. When labor is prolonged and there is no obvious reason for it, a constriction ring is to be suspected. The character of the uterine contractions is characteristic: they are painful and ineffectual, often irregular, and the presenting part does not fill the lower uterine segment even during a contraction. Absolute diagnosis, of course, can be made only with the examining hand in the uterus. In the treatment I have been influenced by the fear that the constriction ring would grow continuously worse, and I have therefore attempted to deliver the patient as soon as I have made the diagnosis. In accomplishing this, the subcutaneous injection of epinephrine has been of great help. Only once has it failed me in relaxing the constriction ring. Of my 112 cases, thirty occurred before I began the use of epinephrine and eighty-two after that time. My own maternal death occurred before the advent of epinephrine. The only Porro section was in a case in which the epinephrine failed me. In the light of Dr. Rudolph's work, this probably should have been treated more conservatively. I have had thirty-one fetal deaths in the whole series, a fetal mortality of 27.7 per cent. In the thirty cases before the epinephrine, there were eleven fetal deaths, or 36 per cent, and in the eighty-two cases after the advent of epinephrine there were twenty fetal deaths, or a mortality of 19 per cent. My largest group, of fifty-three cases with ten fetal deaths and no maternal deaths, approaches Dr. Rudolph's ideal figures for conservative treatment; that is, 2 per cent maternal mortality and 15 per cent fetal mortality. I am of the opinion, therefore, that if the constriction ring relaxes with epinephrine one should deliver that patient in the most conservative manner possible; otherwise one should follow the conservative plan as outlined by Dr. Rudolph.

DR. W. T. PRIDE, Memphis, Tenn.: My terminology is different from Dr. Rudolph's. I tried to establish the fact that there is a difference between a constriction ring and a retraction ring. Some years ago the late Dr. Williams proved conclusively that long muscle fibers from the uterus, when stimulated, would contract at any portion. This proved conclusively that Bandl's ring was a contraction ring and that it can occur at any portion of the uterus. On the other hand, a retraction ring always occurs in the same place, at the junction of the upper and

lower uterine segments, for the reason that these long fibers retract, pulling the short circular fibers, apparently trying to expel the fetus from within. Instead of it occurring at the internal ring, it contracts the circular fibers and pulls them in. It is like closing a tobacco sack; it shuts down around the presenting part. This defines a retraction ring from a contraction and constriction ring, in that the upper portion of the uterus is very tense and not only very tense but painful. A constriction ring, according to my idea, is like a string tied around the middle of the uterus or the lower part of the uterus: it is soft above and soft below. It is a matter of time when relaxation occurs and the patient is in no danger. With a retraction ring one could not expect to relax the upper portion without relaxing the lower; therefore, whenever the tenseness of the uterus disappears, the ring has disappeared. I feel that the maternal death rate has been too high. In a series of 118 cases looked up before the meeting there was no maternal death rate. The fetal death rate was about 12 per cent. I feel that in time this ring and its treatment will be understood. I am having very little trouble with retraction rings because I am giving complete analgesia.

DR. PERCY RUSSELL, Memphis, Tenn.: I agree heartily on the question of diet. However, I insist that the nurses feed these patients every two hours with a liquid diet containing 300 Gm. of carbohydrates, 125 Gm. of proteins and 75 Gm. of fats. The fluid intake is approximately that of Dr. Rudolph's. Most of the nonresident cases that come into the John Gaston Hospital present abnormal presentations or prolonged labors. Often, but not always, do these patients have a retraction ring on admission. I notice in Dr. Rudolph's paper that this possibility should be taken into consideration in antepartum care; I do not believe it necessary if proper management is given during labor. There is one point which I should like to stress and that is the question of lactic acid acidosis. When a muscle is in tetanic contraction, lactic acid accumulates in that muscle. The result is a cramping of that muscle. I try to prevent this lactic acidosis. When a patient comes in with a constriction or retraction ring, as I prefer to call it, she is given either 1 or 2 per cent sodium bicarbonate solution, from 200 to 250 cc., provided she has had no dextrose previously. If that is the case, or, if the patient is given intravenous dextrose or a hypodermoclysis of dextrose solution, she is treated for lactic acidosis with one ampule of Hartmann's solution diluted to 500 cc. For the criterion I do not use an acetone determination on urine. I use the diacetic acid test, as well as the carbon dioxide combining power of the blood. Without fail I have found that within three or four hours a retraction, constriction or contraction ring, as one wishes to call it, will release. The patient will deliver and live. Dr. Pride has mentioned the maternal mortality as nil. The fetal mortality, of course, is greater. The manner of emptying is spontaneous, and seldom is it found necessary to undertake operative procedures, unless there be an abnormal presentation.

DR. LOUIS RUDOLPH, Chicago: Dr. Pride brings up the polemic of the lower uterine segment. The frozen sections of Bumm and Blumreich and of Holland have confused the polemic. It will be essential to study the lower uterine segment on the basis of comparative anatomy and physiology in order to give enlightenment on the location of the physiologic retraction ring at term and at various stages of labor, and its relation to the constriction rings. In some cases reported, I note permanent constriction rings which are not related to the longitudinal muscular changes of the uterus, so that there is no evidence from frozen sections or from living pathologic specimens that the human uterus has the property of transverse contraction, except to correlate comparative anatomy and physiology (particularly of the dog and rabbit) to understand transverse contraction of the human uterus. The biologic basis of this complication as a constriction ring dystocia appears to be sounder than the controversial polemic of the ring of Bandl, constriction ring of Schroeder, or the retraction ring of Barbour and Lusk. Dr. Russell has raised the very important point of lactic acid. I wish to emphasize this point: Constriction ring dystocia occurs early in labor when inanition, dehydration and loss of rest or sleep is not a factor. This complication is rather the underlying cause of the prolonged labor and is due to a pathologic functioning of the uterus,

26. This subject was completely discussed and the treatment recopied from my paper in the *Journal of Obstetrics and Gynecology of the British Empire* 42: 992 (Dec.) 1935.

19 to 25. The autopsy report<sup>37</sup> read: "Upon very careful examination, a minute serous canal, not more than a line in breadth when opened, was traced extending from the internal ring along the spermatic cord into the tunica vaginalis, being the remains of a congenital inguinal hernia."

It is important to remember that the fascia and muscles of the inguinal region in an oblique hernia may be normal and well developed, and there need be no fascial or muscular defect in the early reducible case. Practically, in oblique or indirect inguinal hernia the most essential part of the open operation is closure of the neck of the sac, and simple ligation and removal of the sac give a satisfactorily high percentage of cure.<sup>38</sup>

In a reducible oblique hernia the contents of the sac are reduced into the abdomen; the sac itself is almost never reduced. With a patient in the prone position, or with a truss pad compressing the inguinal canal of a reduced hernia, there is practically no defect, and the walls of the sac are in contact with each other. As the hernia descends, the walls of the canal are pushed apart, forming a functional defect. Therefore, if one can accomplish in these cases the closure of the peritoneal portion of the vaginal process, i. e., obliteration of the hernia sac, cure should result without further ado. With the sac completely emptied, the walls lie in close contact with each other, and they should adhere to each other and thus obliterate the empty sac as such if an irritant is introduced to provide an inflammation or fibroplastic proliferation. This is what is done when a catgut ligature is introduced about the neck of the sac.

The irritant provided may be chemical. The injected solution may be deposited either within the sac or about the sac, usually the latter. In either event an aseptic local peritonitis involving the sac wall is produced. The walls of the emptied sac are kept in constant contact by strong pressure of a truss, which also provides constant pressure on the walls of the inguinal canal. If, throughout the inguinal canal, with the maintenance of such compression, an irritant chemical is introduced, the fibroblastic process described may produce, in addition to the obliteration of the sac, which may suffice for a cure, the binding together of the walls of the canal and also the contents of the canal, into one more or less solid whole. The contents of the canal are chiefly the spermatic cord and its coverings, external and internal spermatic fascia, which are mainly connective tissue. The usual precaution of preliminary aspiration assures avoidance of a blood vessel. Insertion of the needle point or fluid into the vas is productive of exquisite pain and is thus warned against. Scar tissue formation about the vas apparently does not affect the lumen, as any surgeon who has dug a vas out of dense scar tissue of a recurrent hernia may testify. The inner lining of the vas remains, as a rule, uninjured, so that the lumen is preserved.

#### CONCLUSION

The hernia cases for injection treatment must be suitably selected. The most promising results are obtained in patients with oblique hernias which are easily completely reducible and which can be readily kept reduced by a truss. Small recurrent and small direct hernias may be successfully treated. The surrounding tissues must not be atrophic or atonic. It should be pointed out that proper fitting of the truss is of greatest importance. It must feel comfortable and firmly retain

the hernia under all conditions. It is obvious that the pad must fit over the internal ring in oblique hernias, not press on the pubis, and otherwise fit properly.

The technic of injection, adequately described elsewhere,<sup>28</sup> involves an accurate knowledge of the anatomy involved. I experimented with injections of methylene blue in cases prepared for operation and in the first few attempts was astonished at the failure of the injected solutions to be at the expected sites. With experience, the injection at the internal ring may be made quite exact, and such experience should first be gained. The solution used should be one that does not require large doses, preferably not over 0.5 cc., for it is too easy to inject into the peritoneal cavity. Knowing of no better solution at present, I use one of phenol 40 parts, alcohol (95 per cent) 35 parts, oil of thuja 25 parts. The only complication I have encountered has been mild swelling of the scrotal contents, which subsided spontaneously in a few days.

A large number of patients who reject surgery, and who would otherwise go untreated except perhaps for a truss, will submit to the injection treatment. In proper hands, in carefully selected cases, the method is valuable; abuse is extremely easy and can cause general condemnation.

## GIANTISM

### REPORT OF A CASE

CHARLES D. HUMBERD, M.D.

BARNARD, MO.

Of 124 letters and cards requesting reprints of and/or making comments about a recent paper<sup>1</sup> on giantism, seventy-one informed me of a remarkable schoolboy giant at Alton, Ill. This giant has received much newspaper and magazine publicity; my clippings about and photographs of him, over a period of eight years, fill two large scrapbooks. But the popular accounts of his height vary so much in stating his dimensions that their accuracy was questionable. I recorded the following history and measurements at his home, June 2, 1936:

R. W., a white youth, single, aged 18 years 3½ months, is just completing the first semester of his freshman year in college. He is a precromegalic giant, 8 feet 3¼ inches (252 cm.) tall, of phenomenal size, molded on a vast scale, colossal and stupendous in bulk, truly Gargantuan in all his proportions, and symmetrically built. His family home is a small and modest house with ceilings 8½ feet high; he stoops through its doorways and picks his way about among the light fixtures. His oversized armchair and bed have been especially made, but they seem too small for him. He has been bothered much by the curious, who want to see such a freak. His parents have come to resent these intrusions of the inquisitive; they would like to have the lad regarded as an ordinary 18-year-old boy, and physicians and laymen alike find it impossible to do this. Both the giant and his mother are unduly resentful of the fate which has fashioned him on so preposterous a scale. He makes his pocket money by posing for photographs, for which his charges are variable and modest, but certain.

He objects to being measured or to talking about himself and says there is "nothing in it" for him; a lavish and continued expenditure of much cajolery, flattery, servility, wheed-

I am indebted to Drs. David P. Barr and Louis H. Behrens of St. Louis and to Dr. J. E. Walton of Alton for their discussions and suggestions and for their kindness in furnishing me with their data on the Alton giant, whose height exceeds that of every other documented case of giantism on record in medical literature.

There was no evidence to show that either type of treatment modified the course of the disease. In view of the excellent results reported by Foshay it is regretted that some of this group were not given the specific antiserum early during the acute stage. Suppurating glands were usually incised only after they showed definite fluctuation. An attempt was made in a few cases to avoid incision by aspirating and washing out with physiologic solution of sodium chloride the large, soft, fluctuating gland masses. It proved successful in three cases but in some instances the procedure was followed by a febrile reaction and even a chill. Two patients whose adenitis persisted for unusually long periods were treated with high voltage roentgen therapy.

The average period of hospitalization for the entire group was ninety-eight days, for the serum treated cases 100 days, and for those treated with mercurochrome 101 days. These periods of hospitalization are considerably longer than one would expect in civil practice, where the matter of expense and the necessity of earning a livelihood would prevent such prolonged hospital care. There were no deaths. All the enrollees, twenty-seven in number, were finally restored to duty. They showed an average gain in weight of  $7\frac{85}{100}$  pounds (3,560 Gm.) while under observation.

The laboratory tests to which they were subjected gave very significant results. Nearly all the patients had three tularensis agglutinations, one in the second or third week, during the acute phase of the infection, a second during the fifth to the eighth week, and a third during the ninth to the eleventh week of the disease. The early agglutinations were done by the macroscopic method, and in only one dilution, 1:40. Notwithstanding this low dilution, some cases, which later showed very strong agglutinations, were negative. Others were feebly to strongly positive. From the fifth to the eighth week complete agglutinations were obtained in every case in dilutions of 1:160 up to 1:1,280, with an average of 1:650. The later agglutinations, i. e., during the ninth to the eleventh week, were usually, though not always, weaker, the average titer in which complete agglutinations were obtained being 1:370.

Melitensis agglutinations and complement fixation tests were also performed. Only two suggestive results were obtained, a moderately strong melitensis agglutination in a dilution of 1:160, with a negative complement fixation test in one patient, and a strongly positive complement fixation test, with a negative agglutination test in another. Neither case gave a history of any previous illness suggesting undulant fever.

Skin sensitivity tests were performed with equally interesting results. One-tenth cubic centimeter of nitrated tularensis antigen, containing approximately ten million organisms, was injected into the skin of the forearm, and the reactions were read after forty-eight hours. Nearly all cases gave strongly positive results, the reactions being considered negative in only three instances. In two of these negative cases the agglutination titer at the time was 1:160; in the third the agglutination was negative.

In discussing the treatment of tularemia, Foshay states that his antiserum has a specific desensitizing effect. In our patients it was found that those treated with Foshay's serum showed more rapid diminution in agglutinative titer and less marked reactions to *Bacterium tularensis* antigen intradermally than those not so treated. Though our results were not striking, they were in line with Foshay's observations.

Because of the characteristic lymph gland involvement found in granuloma inguinale, it appeared possible that some relationship between it and our cases of tularemia with lymphadenitis might be demonstrated. Intradermal tests with Frei antigen prepared from granulomatous lymph glands were done. All the tests were negative, indicating so far as this limited study was concerned no relationship between the two diseases.

Several attempts were made late in the disease, during the sixth to the eighth week, to recover *Bacterium tularensis* from abscessed lymph glands. Pus aspirated with a Luer syringe was injected repeatedly into guinea-pigs. Abscessed lymph glands were emptied by aspiration, gently massaged to break down partially the surrounding abscess wall, again aspirated, and the bloody necrotic material used for cultural experiments and guinea-pig inoculations. And in a further effort to obtain the organism, swollen but nonsuppurating glands were aspirated, and the serum obtained was subjected to similar tests. The results were always negative. They support the clinical observation that there is little danger to the physician who handles such cases.

It appears reasonable to attribute the transmission of the disease in this epidemic to the deer fly. This insect is a proved vector of the disease. Past experience has shown it to be the principal means of transmission in Utah. The patients stated that deer flies had become much more prevalent a week or two before the first enrollee became ill with tularemia. The flies were so numerous that each enrollee suffered not one bite but many bites every day. In many instances hard biting flies were instinctively slapped and crushed on the skin. Jack rabbits were also numerous; many were found dead without evidence of violence and others appeared sluggish and in poor condition. It is significant that nearly all the enrollees infected were young men, working stripped to the waist at some distance from camp, that older, less vigorous men employed in the camp itself as overhead personnel, about thirty-five in number, kept their shirts on, and that of this number who were not continuously out on road and dike work none contracted the disease. In other words the vector was some biting insect that attacked the bare skin of men at work away from camp, where sick rabbits were in evidence and deer flies numerous.

None of the enrollees had eaten rabbit flesh, but thirteen of the victims had killed rabbits or played with dead ones. One enrollee had even removed the ears and had carried them in his pocket for "good luck." Yet not one patient showed a point of infection on the fingers or hands. That ticks were not responsible is shown by the location of nearly all the primary lesions on the uncovered portions of the body, and not on the thighs, perineum or lower part of the abdomen.

Mosquitos were prevalent. A sanitary inspector in a report made early in June commented on the number of mosquitos and stated that mosquito bars, head nets and gloves were all necessary. Had mosquitos been a major factor in transmitting the infection, cases would probably have appeared at an earlier date. The belief that mosquitos were not important as vectors of the disease is in accord with the observations of Philip, Davis and Parker of the United States Public Health Service, who, after conducting a series of careful experiments on the transmission of tularemia by mosquitos at the Rocky Mountain Spotted Fever Laboratory, Hamilton, Mont., reached the conclusion that in nature the mosquito transmission of tularemia is rare. The method of infection of the young woman who

His walk is a slow, laborious, shoulder-hunching shuffle. Like most other giants, he is especially prone to trophic ulcers and indolent infections of the feet, which have caused him much grief. All sensations (touch, pain, temperature) are void and blank below the ankles, and the loss of pain and temperature senses affects also the middle third of the lower legs. There is a loss of temperature sense, too, up to the level of his knees. His own explanation is that his "legs have grown too fast for the nerves to keep up." It is possible to conceive of his diminished sensibility arising from a "standard" number of ordinary pain areas being distributed over a skin with the surface area more than twice the normal in size. He is unaware of a wrinkle in his sock or a foreign body inside his shoe until a blister, followed by an ulcer, is formed, and only then do the general symptoms of a systemic reaction arouse him.

Roentgenograms of the skull show the air spaces of the paranasal sinuses and mastoid cells developed to an unusual size. The sella turcica is very large, and its floor is pierced by a tubular structure (persistent Rathke's pouch) which extends downward and forward through the sphenoid to the posterior wall of the nasopharynx, where an indefinite soft tissue shadow bulges into the lumen. He must have a most extraordinary amount of functioning pituitary tissue. The mental reactions

suggest involvement of the frontal lobes, and pressure on the pons posteriorly could well account for his loss of sensory perceptions.

The hospital records, 1931-1935, of his blood studies show an average of about 4 million red blood cells, 7,000 white blood cells and 75 per cent hemoglobin; the Kahn and Wassermann tests were negative. Urinalyses have all been negative except for a rather high specific gravity and the presence of acetone during a starvation period in April 1935 (Simmonds' disease?). The blood sugar was 134 mg. June 30, 1932, 89 mg. March 25, 1935, and 112 mg. April 8, 1935. The basal metabolic rate was minus 18 per cent in 1932 and in 1935.

His anthropometric picture is given in table 2. His present weight, he says, is 395 pounds (179 Kg.) in ordinary clothes.

The thick lips, coarse nose, increasing depth of the chin and general enlargement of the soft parts of the face, as noted when earlier photographs are compared, suggest that an acromegalizing process is already beginning and can be expected to become prominent in the near future.

Anthropologists have yet to set up a definite height above which a man can with certainty be labeled a giant. A scant 10 inches (25 cm.) added to the crown-heel length of an ordinary 6 footer sets him far apart from the crowd and gets him the attention always bestowed on giants by the public. A 10 gallon hat and a pair of high heeled boots equipped with "lifts," with some 82 or 83 inches (208 or 211 cm.) of height

furnishes the picture of more than half of the giants seen in today's sideshows. It is of interest to read that Phineas T. Barnum, doyen of American showmen, after expressing a doubt that there were any men of 8 foot (244 cm.) stature, carefully instructed a friend who was acting as his agent in hiring a French giant<sup>3</sup> to give the tall man a job only if his height, as measured when the bootless giant lay flat on the floor, exceeded 7 feet 2 inches (218 cm.). Just why the impresario chose that figure is not known; probably a giant of this height had been in his employ previously. This boy at Alton could indulge himself in the luxury of a 13 inch slouch and still get on the payroll of a later-day Barnum.

The height limit of the U. S. Army in World War days was 6 feet 6 inches (198 cm.). Among 3¾ million men between the ages of 18 and 30 (a relatively larger proportion of them between 21 and 30) only seven cases of giantism<sup>4</sup> were found. I have been unable to identify these seven cases, for only a little information about them is to be had from the tedious tables of the work cited. But four of these giants were accepted for full army service, in spite of their disability, so it must be presumed that their heights were not greatly in excess of the army's standard. One of the four was a Negro from the Mississippi River bottoms of rural Arkansas<sup>5</sup> and the other three were white. One of the three came from a rural section in the northern half of Minnesota,<sup>6</sup> where the population was 10 per cent Scandinavian, another came from a rural section in the southern half of Minnesota,<sup>7</sup> where the population was more than 20 per cent German and Austrian, and the last, a native white Southerner, came from eastern Oklahoma<sup>8</sup> where, in a rural district, there was a sparsely settled Indian territory. Perhaps these men became drum majors for army bands. Their roster does not seem to include Homer Parks of Memphis, Tenn., who is still regularly exhibiting as a circus giant under a banner which extols him as being the tallest soldier overseas. He makes an imposing spectacle in American Legion parades.

Of the three men whose giantism was sufficient reason to reject them from army service, one was a white mountaineer in a rural district of eastern Kentucky,<sup>9</sup> a second came from an urban district in section 2 of Louisiana,<sup>10</sup> and the third came from Washington<sup>11</sup>; the exact locale is in doubt, since the earlier references assign him to an urban district, while the later ones place him in a rural section. Tracing these giants must be left to some one who knows the ins and outs of War Department officialdom and the whereabouts of record cards there. I have been told that the statistical cards used in compiling the data were destroyed. The material of the text cited must be incomplete, for I have competent evidence that Bernard Coyne (1897-1921), an undescribed 7 feet 8 inches (234 cm.) giant of the infantilism type who lived on a farm near Oto, Iowa, appeared before the examining board at Des Moines in the draft routine of 1918 and was rejected because of his giantism.

reported having eight years previously treated thirteen cases, he also stated that he did not follow the cases longer than a few months, did not deem the method of sufficient importance for special publication, and in a very short time abandoned the treatment. Heaton<sup>15</sup> wrote a book on the injection treatment of hernia. He received European honors, specialized in his own "rupture" hospital in Boston, claimed hundreds of cures, and amassed a fortune. He was in disrepute with the American Medical Association because he kept his treatment secret. His claims were not accepted at the time,<sup>16</sup> and when he finally published his book it revealed unique ideas concerning anatomy and pathology. He was considered a "blatant and notorious charlatan" by Manley, and his only disciple, Warren,<sup>12</sup> admitted exaggerated claims on the part of Heaton. Nevertheless, he apparently did obtain a certain number of cures with his fluidextract of white oak bark. No reputable writer of that time or later accepted his work, although lack of such acceptance by the ethical profession as a whole did not, of course, result in its oblivion. The treatment by injection was taken up by innumerable quacks, and indiscriminate use resulted in deaths.

Reminiscent of the present trend, Warren<sup>12</sup> wrote and talked much in the years 1881 to 1884 and published his first paper within a few months after his first injection, and a book on the subject within a year. Similarly Schwalbe<sup>17</sup> in 1875 in Germany, who had used 70 per cent alcohol as a sclerosing agent, hastened to publish descriptions of his cases, and his first article reports three cures. His second paper cites four cases, two still under treatment. He later reported a large percentage of cures in many more cases. Many single case reports appeared, usually with a change in the chemical employed. Perhaps an extreme instance of the desire simply to innovate and to write is the use, as the injection material, of a *Bacillus pyocyaneus* culture.<sup>18</sup> Enthusiasm flamed and subsided; the articles published remained to be quoted.

#### STATISTICS OF CURE

On the other hand, articles have appeared in the past few years in which are presented thousands of treated cases. The claims are most enthusiastic, frequently without support of statistics. Where the latter are presented, they seem to be, as statistics everywhere, at least often questionable, as regards both the percentage of cases found suitable for treatment and, more important, the percentage of cures.

Contraindications to treatment have been generally agreed to include hernias associated with undescended testicles, irreducible hernias, those which cannot be continuously and perfectly retained by a truss, and sliding hernias. To these should be added other diseases local to the inguinal region, such as lymphadenopathy, and such general constitutional conditions as blood dyscrasias, carcinomatosis, active venereal diseases, obesity and a low intelligence quotient, or psychiatric maladjustment preventing thorough cooperation. The patient must wear a truss kept in an exact position continuously for twenty-four hours a day for a period

of months. He requires as a rule from four to fifteen or more injections and even more clinic visits. If the truss fits properly, the patient is thereby immediately made comfortable, often sufficiently so, in his mind, to render return for injection unnecessary. Finally, I consider as unsuitable for injection, as indicated later, hernias presenting atrophic atonic tissues, and hernias as those in the direct inguinal type in which cure depends on "filling in" a sizable defect. Altogether the foregoing factors are responsible for a high percentage of unsuitable cases, and the percentage of hernias so often reported suitable for injection treatment seems abnormally high.

As to the percentage of cures, follow-up work on ambulant cases of hernia requiring from months to years is difficult and expensive. Special effort and special personnel are required and under the very best circumstances does not reach 100 per cent efficiency. Figures that are offered should be based only on cured cases actually observed for a sufficiently long period. Reports in the literature of up to 100 per cent cure, as will be referred to, do not indicate satisfactory follow-up work. The latter may be rendered difficult by the varied type of patient. The clinic patient may be a confirmed transient, psychopathic, uncooperative alcoholic, or one who for an unknown reason discontinues visits. He may feel sufficiently comfortable after the application of a well fitting truss and a few injections to discontinue his subjection to even the slight unpleasantness of the injection and the wearing of the truss at night. He may become ill from other causes during the long treatment. He may even get a job in the meantime; or the private patient may lose his position or change his physician. Finally, the patient with the recurrence is the most difficult to follow; he often goes elsewhere or loses interest. These are the difficulties with which I have had to contend in my own clinic, and I do not doubt their general applicability. All in all, at the end of a year there is left for analysis a disappointing percentage of the original number treated. This percentage is found still smaller when an attempt is made to trace the cases after two years.

My own clinical experience with the injection treatment extends over a period of two years in connection with a large active hernia clinic and my private practice. Of several hundred hernia cases seen, the number selected as suitable, in which cooperation was actually obtained for treatment and follow up, is as yet too small to submit for statistical analysis. In many cases insufficient time has elapsed for a final estimate. Many clinical cures, by any test, have been obtained; the failures were chiefly in the direct inguinal type.

Heaton claimed 100 per cent cures. Warren never saw a recurrence after he pronounced a case cured! In Switzerland, Steffen<sup>19</sup> reported a 66 per cent cure in 1,372 hernias; Wollerman,<sup>20</sup> a 92 per cent cure in 544 cases. Wyss<sup>21</sup> reviewed 4,632 cases of injection for hernia, of which 3,048 were available for statistical analysis, including 2,775 inguinal and 309 crural, umbilical and ventral. He concluded that cure was obtained in 91 per cent of the cases. Wyss reported complications in 4 per cent, including abscesses, and in two cases of orchitis with atrophy of the testicle.

subsequent treatment with thyroid extract and iodine, if necessary, will be much more easily and pleasantly handled than with attempts at adjustment of the patient by other means to a poorly functioning and most certainly disordered gland containing diseased tissue.

Iodine is the efficient constituent of any of the compounds containing it. There is no particular advantage in any one of them. When it is used in the form of compound solution of iodine we have found orange juice to be the best tolerated of all vehicles. The potassium or sodium salt is equally effective and may be excellently disguised in the new raspberry syrup. These points are mentioned because of their importance to the patients and as an exhibition of elegance in therapeutics.

One of us (Groat) has for many years administered from one third to two thirds grain (0.02 to 0.04 Gm.) of iodized calcium daily whenever thyroid extract is administered. With others, he believes that the action of the extract is improved and its effect smoothed by the coincidental administration of such comparatively small doses of iodine.

We realize that this presents a rather cursory survey of the legitimate uses of iodine in diseases of the thyroid gland. It indicates, however, the need for an understanding of the action of this chemical when its use is contemplated in the treatment of toxic thyroid states.

The statement that it should then be used only in the preparation of the patient for operation, and perhaps postoperatively, is heartily echoed by those who have had to deal surgically with patients who have had temporizing treatment which included the improper administration of iodine.

## Clinical Notes, Suggestions and New Instruments

### SEQUEL TO TREATMENT WITH PHOTODYN

H. F. BLUM, PH.D., BERKELEY, CALIF., AND  
H. J. TEMPLETON, M.D., OAKLAND, CALIF.

An unpleasant sequel to the treatment of a condition of melancholia with hematoporphyrin hydrochloride (Photodyn<sup>1</sup>) has recently come to our attention. This was a severe urticarial response followed by intense pigmentation of the skin resulting from exposure to sunlight two months after the use of the drug. The response appeared in a region corresponding to the probable point of injection of the drug, and its similarity to the effects which we have obtained by injection of this substance into the skin and subsequent exposure to sunlight leaves little doubt as to the cause of the response. Since this drug is being frequently used in the treatment of mental disorders of depressive type, the possible sequelae should be brought to the attention of those who may employ it. We have nothing to say as to the merits of the treatment, on which we have no basis for the formation of an opinion, but we feel that the properties of the substance should be more fully understood.

#### CLINICAL ACCOUNT

Mrs. R. E. S., a white American housewife, aged about 48, consulted us May 23, 1936, because of several pigmented areas on her arms. She stated that these areas appeared Feb. 21, 1936, as angry, pruritic, elevated wheals immediately following her first sunbath of the season. She stated that they began at the sites of injection of "Photodyn," of which drug she had received about eighteen injections between Nov. 15 and Dec. 15, 1935. The first day the three areas were "like hives or insect

bites." The next day the wheal element had disappeared, leaving erythema in its wake. This erythema persisted for two or three days and was followed by brown pigmentation. There was no history of drug ingestion other than the Photodyn.

Inspection revealed a mottled brown pigmented area, 2 inches in diameter, over the insertion of the right deltoid. Near the same area on the left arm were two similar spots each measuring about 1 inch in diameter. None of the lesions were indurated. Pruritus was absent. When seen five months later, the pigmented areas were still present but had faded somewhat.

#### RESPONSE TO INTRADERMAL INJECTION OF PHOTODYN

We have made numerous injections of Photodyn into the skin of normal individuals in the course of investigations of the photosensitizing properties of the porphyrins. The procedure is to inject intradermally a small quantity of Photodyn diluted 1 to 20<sup>2</sup> with salt solution or phosphate buffer. Whealing usually follows the injection, which recedes rapidly leaving a small area at the point of injection slightly colored red by the hematoporphyrin. On exposure to sunlight for several minutes an itching wheal appears over this area, which fades in an hour or so, being followed in a few days by pigmentation, which varies in intensity with the magnitude of the urticarial response evoked. The pigmentation may be very intense and persist for several months. If the injected area is protected from the light, no response is produced.

In one case the sensitivity of the injected area persisted for as long as nine weeks, but we have seen no evidence of sensitivity after this time, and ordinarily there are no further sequelae. However, in one case which had shown no unusual initial response, a long exposure to sunlight on a bright day nine weeks after the date of injection was followed by the appearance of numerous small papulovesicular eruptions at all the points of injection, these being plainly marked by the pigment that had resulted from previous exposure. One of the areas excised and sectioned showed microscopic structure similar to the lesions of hydroa vacciniforme. All the remaining lesions disappeared in the course of two weeks; some of them, however, formed crusts and left tiny scars. In the other individuals injected no such response was observed.

#### COMMENT

The general similarity to results obtained in experimentation leaves little doubt as to the cause of the urticarial response and pigmentation in the case reported, and there is likewise little doubt that such events may be expected if the patient is exposed to intense sunlight within a considerable period after injection of hematoporphyrin. Such a response, when not anticipated by the patient, might produce considerable alarm, as in the present instance, and it seems important to give warning of the possibility of such an event at the time of administering the drug. The appearance of a papulovesicular eruption, such as resulted in the experimental case, might be even more disturbing, and when one realizes the disfigurement caused by the lesions of hydroa vacciniforme which allegedly result from the photosensitizing action of porphyrins, the possibility of such an occurrence should be carefully guarded against.

In this case it seems probable that in the intramuscular injection of the hematoporphyrin some of the substance got into the skin itself and was held there, its presence being made known only on subsequent exposure to sunlight; it is probably impossible to prevent such extravasation into the skin when injections are made. It should be called to attention, however, that sensitization of the skin of the whole body to light may result from the injection of this drug. Meyer-Betz<sup>3</sup> injected 0.2 Gm. into his own vein and produced a sensitivity to light which lasted for two months. While the doses recommended for therapeutic use are much smaller than the dose employed by Meyer-Betz, one must not forget the possibility of a cumulative effect since, as shown, the hematoporphyrin may be held in the skin for a very long time.

Hematoporphyrin belongs to the group of photodynamic dyes of which bengal rose is a member. When living organisms are treated with these dyes and subsequently exposed to light,

2. This solution should contain 0.1 mg. of hematoporphyrin hydrochloride per cubic centimeter.

1. This is the name of the commercial product.

Rice points out that the inflammation produced is exudative and proliferative. He believes that the ideal solution should "stimulate the production of fibroblasts whereby the defect can be filled with scar tissue." Rice has more recently favored for clinical use sodium psylliate, a soap of psyllium seed oil. Stoner,<sup>33</sup> in a very recent article, agrees with the foregoing and states that "the primary object of this treatment is to set up an active seroplastic exudation causing but little inflammation, with the formation of firm fibrous connective tissue proliferation filling and obliterating the hernial tract." In his enthusiasm he recklessly claims that "fibrous tissue formation following hernioplasty undoubtedly plays a much more important part in the cure than removal of the sac, replacement of the cord and the suturing process."

I have repeated these experiments on dogs and rabbits. Muscle and fascia were injected with various solutions of increasing strengths including alcohol, tannic acid and phenol. I also performed biopsies during open operations on patients who had sclerosing injections. On the whole, Rice's observations were confirmed. Irritating alcohol and tannic acid solutions produced an exudate consisting of edema, fibrin deposit and the infiltration of polymorphonuclear cells, round cells, hyperemia and thrombosis. Phenol solutions produced in addition areas of necrosis. Later biopsies showed lymphocytes and fibroblastic proliferation in progressively greater abundance. In other words, injected chemical irritants produced an acute inflammatory reaction which was gradually replaced by chronic inflammatory changes, resulting in the production of new fibrous connective tissue. Generally it appears that the more dilute the irritant the less the exudate, and there is instead a fibroplastic response, or fibroplasia, wherein fibroblasts grow with the production of collagen fibrils. As these mature, connective tissue or scar tissue is formed, the end result of inflammation. Systemic damage is not produced; very frequently no evidence of inflammation can be found after late examination of injected tissues, and finally, clinically, an area of induration even of long standing may undergo resolution.

#### EFFECTS OF FORMATION OF SCAR TISSUE

In short, the experimental work that has been done proves essentially that injection of chemicals is able ultimately to produce scar tissue. How does the new-formed scar tissue cure a hernia? All incisions into muscle and fascia, even those with the most accurate apposition, heal with the production of fibroplastic tissue. "The fibroblasts grow from one surface to intermingle with those from the opposite side, producing collagen fibrils which effect a permanent union. . . . Scar tissue is never as resistant to tension as normal tissue and if present in any amount<sup>34</sup> it may prove to be a vulnerable point in any area subjected to pressure or tension. It is desirable, therefore, to have the least possible amount of scar tissue following abdominal incisions, for example, in order to avoid postoperative herniation through the cicatrix."<sup>35</sup>

There is, therefore, an important distinction to be made in the value of scar tissue—a distinction dependent on the width of the fibrous tissue. This may be illustrated in cases of healing by first intention as contrasted to healing by second intention. In the one, the

defect is narrow and fibroblasts therein are firmly embedded in the normal tissues of the wound borders. These cells unite to form a thin scar, which, as the connective tissue cells mature, contracts still more and thus brings the borders even closer. The muscle or aponeurosis so united may have restored to it its physiologic functions, including the function of support. In the second instance there is a tissue defect with more widely separated borders requiring a greater proliferation of scar tissue simply to fill in the defect. The latter is more likely to allow postoperative hernia even with the anatomic filling in of fibrous tissue, which may be especially abundant as following infection and suppuration. The latter complication in a surgically repaired postoperative hernia would be likely to lead to a recurrence.

From this argument it would theoretically appear that hernias having anatomic defects with widely separated aponeuroses, as in postoperative hernia, in diastasis recti, or in most direct inguinal hernias, cannot be cured effectively by filling in these defects with fibrous tissue, as may be produced with injections of irritating fluids. In actual practice such hernias are not permanently cured, and the injection treatment cannot be recommended for these types. The fibrous tissue filling such a defect may serve "to obliterate" and block a hernia better than no tissue at all, but the fact remains that such tissue in large amounts under pressure is likely to stretch and yield relatively easily. Further, such new tissue can add little to support preexisting muscle or fascia already atrophic, stretched or otherwise atonic. Granting, therefore, the effectiveness of the injected solutions in producing new connective tissue, which is all that the experimental work has proved, it is difficult on theoretical grounds at least to conceive of the cure of an incisional hernia of moderate or large size by this means. A direct inguinal hernia is caused by anatomic failure of support to the abdominal contents at the site of Hesselbach's triangle. The defect is not an absence of fibrous connective tissue, for that is always present, and, in fact, the larger and older the hernia, the denser the fibrous tissue.

#### THE SCLEROSING TECHNIC

On the other hand, it is theoretically possible to explain the cure of oblique inguinal and umbilical hernias by the sclerosing technic. Normally the site of the umbilical cord becomes closed concomitantly with the obliteration of the umbilical cord. An umbilical hernia is a defect in the aponeurosis through which a protrusion occurs. If, in infancy, this protrusion is overcome by some method calculated to keep the contents of the sac within the abdomen, e. g., adhesive tape over invaginated skin, the fascia of the aponeurosis will close at a rapid rate. The addition of a chemical irritant will aid fibroblastic growth and closure.

Similarly, in indirect or oblique congenital inguinal hernia there is a defective closure of varying types of the processus vaginalis. The latter may close spontaneously and disappear even after birth. "Keith states that 4.4 per cent of male infants have a hernia in the first year of life, and Bull found that fully two thirds of these disappear either spontaneously or with the aid of a truss."<sup>36</sup> A truss worn for a long period may accomplish such a cure in infancy and even later. Sir Astley Cooper, anatomist and surgeon, requested that at his autopsy his cured oblique inguinal hernia be investigated. He had worn a truss from the ages of

5.4 Gm. of the drug before the appearance of the eruption. There was no history of other idiosyncrasies to drugs or of allergic states. The patient had tolerated the administration of iodine without incident in preparation for the thyroidectomy eight years before.

The patient was fairly well nourished but moderately ill. He weighed 141 pounds (64 Kg.). The pulse rate was 112 beats per minute, the temperature was 100.2 F., and the blood pressure was 180 systolic, 114 diastolic. The heart was moderately enlarged, with accentuation of the second aortic sound; there was an advanced peripheral arteriosclerosis for a man of his years. A small adenoma of the remaining thyroid tissue was also present.

The Kline reaction on the blood was negative. The value for the hemoglobin and the number of erythrocytes in the blood were normal. The leukocytes numbered 10,400 for each cubic centimeter of blood and an eosinophilia of 5 per cent was noted. The urinalysis showed albumin, grade 2 (on the basis of 1 to 4), and 8 erythrocytes for each high power field. A roentgenogram of the thorax revealed slight congestion in both lungs. The electrocardiographic tracings were indicative of hypertensive and coronary heart disease. The readings for the basal metabolic rate were at first elevated but returned to within normal limits after a period of treatment.

Examination of the skin revealed an acute papulo-urticarial eruption, which was widely distributed over the entire body, except the palms and soles. There was no pruritus. The eyelids were slightly edematous and there was moderate conjunctivitis with lacrimation. The pharynx was moderately congested and the uvula was swollen.

The patient was placed in the hospital for a period of three days and was given large amounts of fluid nourishment and mild alkaline diuretics and cathartics. Within a few days the erythematous character of the eruption subsided and a rather marked pigmentation remained at the sites of the original lesions. There was more or less superficial desquamation in the next few weeks.

Patch tests with 1 per cent aqueous solutions of sodium thiosulfate and potassium ferrocyanide and 2 per cent solutions of sodium sulfite and sodium sulfocyanate were applied for two days to the skin of the thigh, but no local reactions could be observed at the end of ten days. The conjunctivitis, pharyngitis and microscopic hematuria gradually disappeared, and the temperature returned to normal.

#### COMMENT

Claude Bernard<sup>8</sup> almost eighty years ago described experiments which showed the toxic manifestations of sulfocyanates. The pharmacologic and toxicologic properties of the drug have been ably reviewed by Nichols.<sup>9</sup> He calculated, on the basis of experiments with guinea-pigs, that the minimal lethal dose for a 154 pound (70 Kg.) man would be about 15 to 30 Gm. However, the tolerance of the individual patient to the drug varies greatly and many patients have tolerated a much larger dosage for a period of time without showing mental, gastro-intestinal or dermatologic manifestations of sulfocyanate intoxication. In thirteen cases reported by Goldring and Chasis,<sup>3</sup> the total dosage varied from 5.8 to 32.5 Gm. and the duration of medication in days also varied from seven to sixty-nine before toxic symptoms of sulfocyanate poisoning became evident. In the two fatal cases observed by these authors, only 9.7 and 14.5 Gm. had been ingested in fifteen days and eighteen days, respectively. The dosage commonly prescribed is from 0.3 to 1.0 Gm. daily for a period not to exceed three weeks. Barker,<sup>10</sup> in his study of the cyanates in the blood of patients who are undergoing treatment with sulfocyanates, recently found that the optimal therapeutic level would seem to range between 8 and 12 mg. for each hundred cubic centimeters of blood and that significant toxicity became evident at from 15 to 30 mg. It would appear that the toxic effects resulting from sulfocyanates are the result of a true idiosyncrasy to the drug rather than to an overdosage.

The suggestion has also been made that the drug possibly possesses a cumulative action, as it is very slowly excreted in the urine. Healy<sup>11</sup> has suggested an accumulation of the drug in the adrenal glands.

Sodium sulfocyanate is believed to be less toxic than potassium sulfocyanate or ammonium sulfocyanate, but there is little evidence to support this.

The toxic dermatoses that have been reported following the use of sulfocyanates have been, in general, so briefly described that a satisfactory dermatologic picture of this drug eruption cannot be deduced. They apparently resemble either the toxic erythema seen in acute arsenic poisoning or the papulopustular eruption following iodide therapy. They usually appear within ten days after administration of the drug is begun and disappear rapidly after its cessation, often leaving a pigmentation and exfoliation which persist for only a few weeks. However, it is probable that serious consequences might result if the sulfocyanates are not recognized as the inciting cause and if their administration is not immediately discontinued.

#### SUMMARY

Preparations that contain a sulfocyanate continue to be used widely in the treatment of essential hypertension despite the known toxic manifestations. The dermatoses resulting from the use of this drug have not received the attention in the literature which their frequency deserves. Only nine cases have been reported. A case in which a toxic exanthem and pigmentation resulted from the use of potassium sulfocyanate has been reported.

#### REGIONAL ILEITIS (CROHN)

J. DEWEY BISGARD, M.D., AND J. A. HENSKE, M.D., OMAHA

In 1932 Crohn, Ginzburg and Oppenheimer<sup>1</sup> described a disease entity which they termed regional ileitis and which they brilliantly isolated from a previously confused group of benign inflammatory lesions of the intestine. To this original description little has been added besides confirmatory clinical and pathologic observations.<sup>2</sup> Prior to 1932, descriptions of the disease are to be found only under such general headings as "nonspecific granulomas," "benign granulomas" or "infectious granulomas" in the American literature, and as "inflammatory tumors" or "phlegmons of the intestine" in European literature. In 1933 Harris, Bell and Brunn,<sup>3</sup> and Brown, Bagen and Weber<sup>4</sup> reported cases in which the disease involved portions of the intestine other than the terminal 8 or 10 inches of the ileum; namely, the jejunum, proximal ileum and colon. For the disease therefore they suggest the more inclusive names cicatrizing enteritis<sup>5</sup> and nonspecific regional enteritis.<sup>4</sup>

The etiology of the disease has never been established. Some investigators, notably Felson<sup>6</sup> and Jaffe,<sup>6</sup> have presented evidence to show that the primary lesions are produced by the dysentery bacillus. Felson believes that both regional ileitis and chronic ulcerative colitis have a common etiology and are the

ling and exaggerated politeness, and persistence is necessary to secure any information about him. His expression is surly and indifferent, and he is definitely inattentive, apathetic and disinterested, unfriendly and antagonistic. His frequently voiced complaints are "It's not my fault that I am this way," and "I didn't have anything to do with my getting to be like this." His soured attitude has embittered him very much, and he is introverted and morose, though the newspaper stories, usually quoting his school teachers, say that he is very alert and intelligent. His defective attention and slow responses hold for all sensory stimuli, both familiar and unexpected, but he does manifest a vapid interest in seeing any memoranda made by a questioner. All functions that we attribute to the highest centers in the frontal lobes are languid and blurred. He says that he never has any feelings of vertigo or faintness.

His appetite is enormous, and he eats immoderately, his daily food consumption averaging some 6,000 calories and often running to 8,000. He tires very easily and sleeps much.

He was born in Alton of native American stock. His maternal grandmother was obese and had nephritis. None of his known forebears were of unusual height, and all his immediate relatives are of very ordinary stature. He is the oldest of a family of five children; he has two brothers, aged 14 and 3½ years, and two sisters, aged 16 and 12 years. He was described by Drs. Louis H. Behrens and David P. Barr<sup>2</sup> of St. Louis as of July 1931, when he was 13½ years old, as 221.5 cm. tall and endowed with a superabundance of brute strength, and there is little that can be added to their account of his early history. At birth he weighed 8½ pounds (3,856 Gm.), and his birth was the ordinary uncomplicated delivery of a primipara. At 6 months he weighed 30 pounds (13.6 Kg.), and at 18 months his weight was 67 pounds (30.4 Kg.). At 5 years he was 5 feet 4 inches (163 cm.) tall, and at 8½ years his height equaled his father's. He had a bilateral inguinal herniotomy when he was 2 years old. He had measles and chickenpox in early childhood and whooping cough when he was 11. He has not had scarlet fever and and has never experienced any "growing-pains." The history of injuries includes only minor wounds to his feet.

He has been a patient in Barnes Hospital, St. Louis, on four occasions, and his routine records there have been used to supplement my own observations, particularly when his lack of cooperation made laboratory work impossible and some details of his measurements inaccessible:

Oct. 13-23, 1931: Cellulitis of the left foot with incision and drainage by through-and-through drains in the web of the first and second toes: simple anemia.

June 21-July 2, 1932: Old fracture of the second left metatarsal.

Oct. 18-23, 1932: Abscess of the left great toe, with incision, drainage and wet dressings.

March 29-May 4, 1935: Ulcer of the right great toe; epistaxis; sacro-iliac arthritis; cachexia from persistent anorexia and vomiting.

The record of his growth given in table 1 is believed to be reasonably accurate. It has been compiled from several independent sources: the hospital notes (a measurement of his height being necessary for each metabolism determination), the record of measurements kept by his father, the published accounts of newspaper correspondents (with an average deduction of 1¼ inches [32 mm.] for the heels of his shoes, since he was never asked to remove his shoes when he was backed up against sundry walls to have rulers leveled off above his crown), a tailor's specifications and a shoe manufacturer's publicity material, and a long series of photographs the backgrounds of which could be measured and scaled.

It will be noted that this growth curve has been steady and continuous, without noticeable spurts or upsets. One cannot predict when the curve will level off; I think that the lad's height is still actively increasing.

The giant appears to be quite asthenic and more than a little anemic. His musculature is inadequately developed. His general posture is good for his size and weight. His sitting posture is "droopy." His sense of position, for his arms, hands, legs and feet, is very poor. His motor coordination is not good, or else he is unduly sloppy by nature. He is careless in his dress. His handwriting is untidy and poorly legible.

His blond hair is fine and very thick; his skin is fair, cold, moist, elastic and stretched, and very pallid. His eyebrows are thin, and they are not rugged as in acromegaly. He is severely myopic and has a moderate degree of astigmatism, and a divergent squint, which is alternative. He suffered much from headaches before these refractive errors were corrected with glasses. There is no nystagmus. The pupils are round, equal and contract normally to light and slowly to accommodation. The sclerae are clear. There seems to be a slight photophobia, a little drooping of the lids and some lid lag; there is very little contraction of the visual fields. The nose is roughly shaped and rather bulbous, and the nostrils are very large. The nasal septum shows a marked deviation to the right, but the airways are clear. He thinks his sense of smell is normal. His ears share in his gigantic makeup; the pinnae are heavy and flaring. The external auditory canals project themselves upward to an unusual angle into the skull, rather than in the usual course slightly downward and forward. His lips are thick and heavy, and pale. His teeth are very large, regular and evenly spaced and in good condition; the occlusion is good. The palate is unusually high. The tongue is big but not disproportionally so. The tonsils are enlarged and a little injected, without purulent masses. Deglutition seems to be very "violent" and "awkward." His voice is a weak bass, thick, husky and mumbling and comparable to the enunciation of a patient with an acute quinsy. His spine shows only the normal anteroposterior curves, with no lateral deviations. His chest is barrel shaped. The scapular borders are straight, and the curves of the clavicles are straightened out a little from the normal. His heart shares

in his proportions; the apex beat is somewhat diffuse under the left nipple. There is a reduplication of the pulmonic second sound.

His blood pressure has been about 110 systolic and 80 diastolic for five years. The respiratory rate is 18 and the pulse 70. The abdomen is slightly paunchy, rounded and soft, and its wall is rather fat and "loose." It moves freely, and immensely, with respiration. The scars of the early bilateral inguinal herniotomy are in good condition. There is a nocturia of two or three times. The external genitalia are quite small; both testes are descended. The pubic hair is scanty, and there is no body hair. He has no lymphadenitis. His hands, whose measurements will be given later, are startlingly enormous; the metacarpals are so extremely long that the thumb, to appearances, sits noticeably nearer the wrist than it should. At the knuckles the fingers tend to an ulnar deviation laterally, away from the thumb's side of the hand, to a marked degree. His nails are thin. Roentgenograms of the hands show, despite much tapering of the fingers, an abnormal amount of tufting of the terminal phalanges of all his digits. His fingers are "double jointed," and they curl themselves up in bizarre positions and assume ungainly and gruesome postures. His wrists, knuckles, knees and ankles, without being greatly misshapen, still show that they do not function with complete normality as joints; they are enlarged and awkwardly formed. But in the hasty and riotous overgrowth at the epiphyses it is not strange that nature's architecture goes somewhat awry and that the nearby joint surfaces acquire planes with angulations, in relation to the bony shafts, that deviate a little from the normal. This would explain the vagaries of unexpected and odd "twists" in his wrists, fingers, knees and ankles. These joints appear to be swollen, but they do not pit with pressure. There are pigmented scars on his shins. His feet are disproportionately large and he is very flat footed; his toes are misshapen.

2. Behrens, L. H., and Barr, D. P.: Hyperpituitarism Beginning in Infancy: The Alton Giant, *Endocrinology* 16: 120 (March-April) 1932.

down to 160 pounds (73 Kg.). From December 1934 to April 1935 there was a further loss of weight down to 125 pounds (57 Kg.).

When first seen there was a granulating wound over the stump of the left great toe 3 cm. in diameter. On the plantar surface of the foot overlying the first metatarsal bone there was a deep incision about 5 cm. long exposing necrotic tendons. The circulation in the upper extremities was normal. Both femoral arteries pulsated normally. The right popliteal artery was open, the left was closed. The right dorsalis pedis pulsation could be felt. The right posterior tibial was closed. There was no pulsation in the left foot. The oscillometer readings were: calf, left very faint; ankle, left 0, right 2. The general physical examination was entirely negative. The Wassermann test was negative.

A diagnosis of thrombo-angiitis obliterans was made and treatment was begun with intravenous injections of 5 per cent sodium chloride solution. The condition of the foot responded favorably and six weeks after the patient was first seen he was discharged from the hospital with the foot entirely healed. He went away to the country for a month and on his return to the city injections of hypertonic salt solution were resumed. At this time he first began to complain of weakness and occasional vomiting spells. He stated that during the past three months there had been gradually increasing pigmentation of his face. He attributed this to exposure to the sunlight. He also complained of diarrhea. On examination at this time pigmentation was noticed on the mucous membranes of the mouth; the blood pressure was found to be 80 systolic, 50 diastolic. A diagnosis of Addison's disease was made and the patient was readmitted to the hospital. At this time his weight was 107 pounds (48.5 Kg.). There was striking pigmentation of the face, mucous membranes, chest and back, the extensor surface of the elbows, and the anal fold. There were typical black freckles in these areas. The systolic blood pressure continued to range between 80 and 95. X-ray examination of the chest and the abdomen with particular reference to the adrenals failed to show any evidence of tuberculosis. The blood urea was 14 mg. per hundred cubic centimeters, blood sugar 75 mg., blood chlorides 540 mg. and hemoglobin 70 per cent. Many urine examinations were negative. The patient continued to be treated with injections of hypertonic salt solution and in addition was given 6 Gm. of sodium chloride in enteric coated capsules by mouth. He was placed on a high calory diet with increased salt and received vitamins and 30 grains (2 Gm.) of saccharated ferrous carbonate three times a day. He was also given injections of a commercial adrenal extract (eschatin-Parke, Davis & Co.) 2 cc every other day. He continued to lose strength and his weight went down to 93 pounds (42 Kg.).

At this time (September 18) the patient was seen in consultation by Dr. Leonard G. Rowntree, who confirmed the diagnosis of Addison's disease. He stated that the history of the patient, his weight loss, the blood pressure, the pigmentation (buccal, labial, cutaneous, and the black freckles) were all compatible with Addison's disease. The weight loss was about what he would expect from the duration and severity. He could discern no clinical evidence of tuberculosis or syphilis. The cause was not determined. The combination of thrombo-angiitis obliterans with Addison's disease was unique in his experience. It might be due to atrophy on a vascular basis. The outlook was grave, he said, but not hopeless so far as Addison's disease is concerned.

Another adrenal extract, made by the method of Swingle and Pfiffner, was obtained through Dr. Rowntree and the patient was started on 2 cc. of this substance twice a day. With the beginning of this treatment, his weight began to increase and his general condition improved. The blood pressure increased to 100 systolic, 60 diastolic, and remained at this level. At the time of his discharge from the hospital on October 19 his weight was 105 pounds (47 Kg.). His hemoglobin was 80 per cent and the red blood cell count 4,400,000. Injections of hypertonic saline solution were continued at the office twice a week, and the patient took injections of 5 cc. of this adrenal extract daily. Between October

1935 and March 1936 his weight increased to 140 pounds (63.5 Kg.). His walking improved strikingly and he was able to walk ten blocks at a fair pace without pain in his left foot. The left foot remained healed. The oscillometer readings increased to: calf, left  $\frac{3}{4}$ , right 4; ankle, left  $\frac{1}{4}$ , right  $2\frac{1}{2}$ . The systolic blood pressure continued to be about 100.

In April 1936 the patient developed an acute catarrhal icterus. He was readmitted to the hospital at this time. In addition to the icterus, enlargement of the spleen and liver was noted. Intravenous injections of 5 per cent dextrose in physiologic solution of sodium chloride were substituted for the hypertonic salt solution, and the other medication was continued as before. The dose of adrenal extract was increased to 10 cc. daily. The jaundice cleared up completely in a few weeks, and the liver and spleen returned to normal size. Following the suggestion of Wilder and his co-workers<sup>1</sup> of the Mayo Clinic, a low potassium diet was prescribed. The patient was discharged from the hospital at the end of May weighing 142 pounds (64 Kg.). He has continued in excellent general condition to date.

#### COMMENT

The occurrence of two diseases in a single individual is always of interest, particularly when the two conditions are so rare as thrombo-angiitis obliterans and Addison's disease. The coincidental occurrence of the two diseases in one person may be regarded as evidence that they are not antagonistic. This information may be of value in understanding the nature of the disease processes.

Although the use of tobacco appears to be the active cause of thrombo-angiitis obliterans, a constitutional susceptibility to this substance is necessary as a background. It is still not clear of what this constitutional defect consists and what mechanism it is by which tobacco produces its harmful results in such individuals. Recent studies of blood volume,<sup>2</sup> chemistry<sup>3</sup> and basal metabolism<sup>4</sup> would appear to indicate that in thrombo-angiitis obliterans there is a tendency to diminished function of the thyroid-adrenal-gonad chain of endocrine glands. The occurrence of Addison's disease in a patient with thrombo-angiitis obliterans offers additional evidence in favor of this conception.

Could the Addison's disease be due to atrophy of the suprarenal glands secondary to obstruction of their blood supply by the vascular disease? While thrombosis of intra-abdominal arteries has been observed in patients with thrombo-angiitis obliterans, this has always been a feature of very advanced and late stages of the disease.<sup>5</sup> In such cases all the vessels in the lower extremities have been occluded, and thrombosis frequently has extended upward into the lower part of the aorta. Isolated occlusion of the arterial blood supply of both adrenal glands by thrombo-angiitis obliterans has never been reported. In this patient the vascular disease is only moderately advanced, and intra-abdominal involvement seems unlikely.

It is interesting to note the unusually good effect that followed the employment of the adrenal extract of Swingle and Pfiffner. Throughout the early course of the Addison's disease, the patient received a high salt intake, intravenous salt injections and 6 Gm. of salt extra each day, along with eschatin, and continued to lose ground throughout. When, however, 5 cc. of the laboratory extract was substituted for the commercial preparation (eschatin) the patient at once began to improve. His weight rapidly increased from 93 to 140 pounds (from 42 to 63.5 Kg.). This is striking evidence of the value of the Swingle and Pfiffner preparation.

THE USE OF IODINE IN  
TOXIC GOITERS

FREDERICK S. WETHERELL, M.D.

AND

WILLIAM A. GROAT, M.D.

SYRACUSE, N. Y.

The feeling that there is a definite trend toward the use of iodine in the treatment of toxic thyroid disease prompts the present discussion. It is to be presumed that there has been no appreciable decrease in the number of cases of diffuse toxic goiter and of nodular toxic goiter during the past six or seven years, yet the number of patients who have been submitting to thyroidectomy has markedly decreased. Furthermore, many who finally come to surgery have suffered from their disease for a longer period than was the case a few years ago. Many of these individuals have been given iodine in one form or another as part of their treatment. In a considerable number of instances they not only have become poor surgical risks but have an increased morbidity element which lengthens both the preoperative and the convalescent period.

It has been pointed out many times in recent surgical literature that the depression years have increased the tendency to procrastinate in elective surgical conditions. Toxic thyroid disease may be said to fall into this category, but only to a degree; for in the light of present knowledge surgery offers the best chance for cure or relative cure in this condition. If one wishes to chance the damage to the neurocirculatory and other vital systems of the body by a regimen of prolonged medical management, the disease may be thus controlled to a certain degree. The economic loss entailed by such a method far exceeds that which accompanies surgical intervention. The consequent morbidity is greater than that following surgery, and, furthermore, surgery in competent hands offers a mortality rate of less than 1 per cent. This mortality rate is made up in the main by two groups of patients: those with large intrathoracic nodular goiters and those with long neglected toxic goiters. In the latter classification falls no inconsiderable number of individuals who have become "iodine fast," who no longer respond to iodine when given as a preoperative preparation.

To sound a warning that the mortality rate of thyroidectomy will increase unless means are found for disseminating information anent the danger of procrastination and in particular the danger of improperly including administration of iodine in the medical management of these cases does not seem out of place.

Definite figures are not available, but personal interviews with many physicians who practice in a district where goiter is prevalent indicate that there is a growing tendency to disregard Plummer's dictum that iodine should be used only as a preoperative preparation. The latter is a dogmatic yet a safe rule. That there are exceptions, as will be indicated later, is recognized. That importunings of the patient should influence the judgment of his physician is inexcusable. That "another will if I do not" is even more questionable logic.

A verbatim recital of some of the interviews and views of individuals on the treatment of toxic goiter would be interesting but hardly fitting. What seems of importance, however, is that those who have graduated

since the time when Plummer presented his hypothesis are more wary of giving iodine to their patients than those of the older group of physicians. This is a fine commentary on the teaching methods in medical schools today but points at the same time to the necessity for persistent postgraduate education.

The pharmacology of iodine need not be reviewed, but it may be said that many of the actions which it exhibits are unexplainable except by the generalizing term "alterative."

The empirical nature of the administration of iodine in thyroid disease is indicated in its action in both toxic and nontoxic goiters. In the former the gland is the seat of a hyperplasia; in the latter, of a colloid increase. In the former is found hyperthyroidism and in the latter often hypothyroidism, yet iodine has a beneficial effect in both conditions. In toxic states the benefit is short lived. This is not as paradoxical as it seems, for it has yet to be proved that an altered secretion is the cause in either hypothyroidism or hyperthyroidism. There is considerable evidence and good opinion that in diffuse toxic goiter the thyroid gland is not the cause *per se* but suffers with or from disturbances of other organs of the body.

The correlation of activity of the various endocrine glands has been proved to an extent that makes one loath to attribute the therapeutic effect solely to action on any single gland. It seems reasonable, therefore, to assume that at least some of the effects of iodine in good sized doses are exhibited because of its action elsewhere than on the thyroid gland itself. The amount usually administered in dosages of compound solution of iodine is much in excess of the needs of the gland.

A true replacement value is exhibited, however, in the colloid gland found in goitrous areas where the relation of lack of iodine in the soil and colloid goiter has been pretty well established. Here, minute doses of iodine tend to correct anatomic changes and altered function in a gland which has suffered from long continued deprivation of a necessary constituent, a deprivation which amounts to a gross deficiency.

Nodular goiter—toxic and nontoxic—is found most frequently in goitrous districts. There seems to be a distinct relationship between these types and diffuse toxic and colloid (diffuse nontoxic) goiter. It may be surmised therefore that here too, when symptoms of hyperthyroidism manifest themselves, one is seeing the effect of a functional deficiency due to a mild, long continued disturbance of the general endocrine balance, nutrition and psychic state.

For this reason we believe that iodine is properly used in small doses for hypothyroidism and colloid goiter. Empirically we believe in its use for hyperthyroidism both as a preoperative preparation and as a postoperative treatment. With a definite understanding of its limitations and dangers, it may be used as an expedient in mild hyperthyroid states and as an aid in differential diagnosis. Whenever iodine is used over a prolonged period of time, its administration should be interrupted for a week or ten days every four to six weeks.

We are thoroughly committed to the idea that all so-called adenomatous goiters are surgical conditions.

Iodine should be used in both nodular toxic and nontoxic types as a preoperative preparation and for assistance in the correction of an obvious functional imbalance. One is dealing in these instances with a gland which in itself is diseased. Surgical intervention should be undertaken in these cases with the idea that

Read before the American Association for the Study of Goitre, Chicago, June 10, 1936.  
From the Departments of Surgery and Clinical Pathology, Syracuse University College of Medicine.

sites (prescription 1). The head is coated thickly with this ointment and washed a half hour afterward. The head covering that was worn by the patient should also be disinfected.

**Softening and Combing Out of the "Nits":** As the ova are not killed by this process and hatch within six days after they are laid and then develop into fully grown lice within two weeks, they must be slipped off the hair shaft. Following the treatment described the scalp is therefore generally treated at bedtime with warm vinegar and enveloped in a rubberized cloth. The next morning the scalp is washed with soap. The eggs are still in place but softened. A fine toothed comb

**PRESCRIPTION 1.—Benzene Petrolatum**

R Benzene .....	1.50 cc.
Petrolatum .....	30.00 Gm.

Apply to scalp freely. (Against head lice.)

removes them from the hair as one removes a ring from a finger. A week of watching must follow to be sure that not one egg is left.

Diluted Acetic Acid added to the suggested mercurial lotion combined with the diligent use of the fine-toothed comb unites all the essential requirements in one simple treatment (prescription 2).

**PRESCRIPTION 2.—Acetous Mercurial Lotion (Strong)**

R Mercury bichloride .....	0.24 Gm.
Diluted acetic acid .....	6.00 cc.
Diluted alcohol .....	120.00 cc.

M. Label: Apply to scalp twice daily followed by use of fine toothed comb. (Against head lice.)

Pyodermitis, if present, is perhaps best treated by Ammoniated Mercury Ointment, applied twice a day. If the lesion is irritable this will have to be diluted with 1 or 2 parts of Simple Ointment.

**BODY LOUSE INFESTATION.—Diagnosis.**—These should be called "clothes lice," as they merely invade the body on their foraging expeditions. They should be sought for in the seams of the clothing, especially where it fits close to the body as over the pectoral and pelvic girdles. These lice are large enough to be easily seen. In addition to the small blood crusted puncta, characteristic of this infestation are parallel scratch marks over the shoulders, around the waist and over the sacrum and the thighs. The presence of these should lead to a search for the lice in the clothing. Delousing measures are important in the prophylaxis of typhus, relapsing fever and trench fever.

**Treatment.**—Disinfestation: (a) The clothing and blankets should be disinfested by autoclave (130 F. for thirty minutes or 140 F. for fifteen minutes). Ironing of the clothing, especially the seams, is much less reliable. (b) The clothing may be soaked in 2 per cent dilution of Saponated Solution of Cresol at a temperature above 32 F. for twenty minutes or (c) dipped in gasoline or in cleaners' naphtha. (d) Sulfur may be dusted on the inner surfaces of the clothing to lessen the chances of reinfestation after it has been subjected to any one of these processes. (e) Fumigation of huts or other places that were inhabited by infested groups of men is quite as necessary as is disinfestation of their clothing, to kill wandering lice, which may live without feeding for as long as ten days. Sulfur dioxide or hydrocyanic acid (CAUTION) gas should be employed. Formaldehyde is useless.

**Cleansing Bath:** A cleansing bath with soap and hot water suffices for the individual.

**Destruction of Ova:** This is especially required when dealing with groups of men. For this purpose a bath and a mercurial lotion (prescription 3) are usually sufficient in body louse infestation.

**Treatment of the Damaged Skin:** If much irritation is present, a soothing application is indicated, such as Calamine Liniment, possibly with an antipruritic agent such as 0.5 to 1 per cent phenol if required to break the pruritus vicious circle (see Pruritus). Ammoniated Mercury Ointment may be used on secondarily infected pyodermitic areas.

**PRESCRIPTION 3.—Acetous Mercurial Lotion (Mild)**

R Mercury bichloride .....	0.06 Gm.
Diluted acetic acid .....	6.00 cc.
Diluted alcohol .....	120.00 cc.

M. Label: Apply to affected parts twice daily. (Against pubic lice.)

**PUBIC LOUSE INFESTATION.—Diagnosis.**—Pubic lice ("crabs") most commonly affect the pubic region, producing itching, papules and secondary excoriations and dermatitis, which may extend to the scrotum and inner sides of the thighs. They may also affect the abdomen and buttocks as well as the presternum and such distal areas covered with short stiff hairs as the eyebrows, eyelashes, beard and axillae. They do not inhabit the scalp. In fair persons or those otherwise susceptible, pigmented macules may be seen at the infested sites. Whenever there is no other obvious cause for itching in the genital region, the lice ova should be looked for with a hand lens. The pediculi are small and lie at the base of hairs, holding firmly to the follicle. The infestation is contracted from intimate contact with those having lice on their clothing or on their bodies.

**Treatment.**—The simplest and cleanest way is to sponge the parts with a 1:2,000 Mercury Bichloride solution twice daily for three or four days in succession; then less frequently, every three to seven days, for two to three weeks. The Mercury Bichloride solution may preferably be made in Diluted Alcohol, and 5 per cent acetic acid (prescription 3) may be added. The much used Mercurial Ointment, even the "mild," is often too strong and should not be used here. A quick immediate cure should not be looked for. The thicker the growth of hair, the more diligently and the longer should the treatment be employed.

To remove nits and pediculi from eyelashes, small forceps should be used, followed with Yellow Mercuric Oxide Ointment.

**SCABIES**

Scabies is a classless infestation. Although seen more often in the clinic, scabies is by no means confined to the poor and unhygienic. It is easily recognized when well marked but is often a problem in diagnosis in the cleanly. Its one outstanding feature, severe itching, should make it a suspect whenever this is a symptom, particularly if it occurs at night. While benign and easily cured, it distresses greatly and may lead to unpleasant complications. Scabies challenges treatment not only of the immediate subject but also of the source and those exposed. Whether in the army or the family, scabies should be treated with a view to the group. Only thus can cross and recurrent infestation be prevented.

**Diagnosis.**—Three characteristics point to the recognition of scabies. The severe itching, usually nocturnal, is first. The type of lesions—the unique, thin, zigzag line—under a lens is a series of black or gray dots usually one-fourth inch long but may be shorter or much longer. Also present may be small papules and a characteristic bluish opal vesicle and scratch marks with small blood crusts. Most reliable is the distribution of the lesion. It is symmetrical, is absent above the clavicles, and avoids the palms and soles except in infants and young children. In men it may involve the

photo-oxidative changes result which are usually destructive to the organism. These oxidative changes all require molecular oxygen<sup>4</sup> and the effects produced in the skin can be separated from the sunburn response of normal skin on this basis.<sup>5</sup> The wavelengths of light which produce the hematoporphyrin response are those absorbed by this dye and lie in both the ultra-violet and the visible regions. The shorter wavelengths which produce the sunburn response do not pass through ordinary window glass to any extent, and such glass will protect against sunburn; but virtually all the wavelengths which produce the hematoporphyrin response will pass through such glass, so that it affords no protection in this case. It should be important to make this clear in warning patients against the effects of light, as a response might be elicited by sunlight passing through a window when the patient is indoors.

Whether the sensitivity to light produced by hematoporphyrin is supposed to play a part in the alleged therapeutic effect is not made altogether clear by the statements of those who recommend it. It is interesting to note from the work of Wolgemuth and Sorenyi,<sup>6</sup> that hematoporphyrin stimulates the use of oxygen by tissues in the absence of light; thus it has some action other than that of a photosensitizer. Bengal rose, on the other hand, does not have such a stimulating effect, although both substances cause the uptake of oxygen in the presence of light, owing to the photo-oxidations which they bring about. It may be mentioned that in our experiments we have found that bengal rose is not held in the skin for nearly so long a time as hematoporphyrin, its sensitizing action disappearing in the course of forty-eight hours. This, together with the fact that bengal rose is excreted very rapidly, accounts for the fact that sensitivity to light does not occur following the use of this dye in liver function tests, except in those cases in which the dye is retained.

#### CONCLUSIONS

From the foregoing account it would seem that, if hematoporphyrin is used as a therapeutic agent, the patient should be carefully warned of the events which may follow exposure to intense light. It should be emphasized that sunlight passing through window glass is quite as dangerous in this case as direct sunlight.

#### DERMATITIS MEDICAMENTOSA RESULTING FROM ADMINISTRATION OF SULFOCYANATES IN THE TREATMENT OF HYPERTENSION

THOMAS W. BAKER, M.D.  
Fellow in Medicine, the Mayo Foundation  
AND  
LOUIS A. BRUNSTING, M.D.  
ROCHESTER, MINN.

Sulfocyanates have enjoyed varying degrees of popularity in the treatment of essential hypertension since their introduction by Westphal<sup>1</sup> in 1924, following the observations of Pauli<sup>2</sup> in 1903. However, much of the early enthusiasm for this drug has waned as its toxic manifestations have become evident. The high incidence of alarming cerebral symptoms in cases in which patients receive either potassium sulfocyanate or sodium sulfocyanate serves as a definite caution against the indiscriminate and prolonged use of either of these drugs.<sup>3</sup> Although

sulfocyanates have fallen into disrepute as a therapeutic agent of any permanent value in the treatment of essential hypertension, they continue to be used freely in proprietary preparations designed to lower the blood pressure.

The dermatoses that result from the use of sulfocyanates have not received the attention which they deserve. From the literature we have been able to collect only nine reports of cases in which some type of eruption occurred following the ingestion of this drug. However, since the observation of the case that is reported in this paper, our attention has been called to a number of similar unreported cases that have been observed by several of our colleagues. It is our belief that the dermatoses resulting from sulfocyanates occur much more frequently than a perusal of the literature would seem to indicate.

In 1926 Takács<sup>4</sup> reported a case in which papular dermatitis followed the administration of 1 Gm. of potassium sulfocyanate daily for nine days. Gager,<sup>3</sup> in his report on the use of sulfocyanate in the treatment of hypertension, barely mentioned two cases in which the patients had "a drug rash similar to that of iodine." Logeheil<sup>5</sup> cited two cases in which the patients had "a severe dry scaling dermatitis with fever and some prostration." Weis and Ruedemann<sup>6</sup> observed a patient who had an acute diffuse toxic erythema associated with edema of the eyelids and followed by an exfoliative dermatitis which, according to them, closely resembled the exfoliating accidents following the use of arsenicals. Their patient had received only 2.7 Gm. of potassium sulfocyanate over a period of ten days before the appearance of the erythematous dermatitis. The exfoliation was complete within a month after the administration of the drug was discontinued. Ayman<sup>7</sup> has recorded a case in which an exfoliative dermatitis developed after the patient had received 4.8 Gm. of potassium sulfocyanate in eight days. Goldring and Chasis,<sup>3</sup> and Borg<sup>3</sup> briefly mentioned two other cases in which a dermatitis developed while the patients, who had essential hypertension, were receiving a preparation which contained a sulfocyanate.

It is our purpose in reporting the following case to direct attention to sulfocyanates as an etiologic agent in the production of toxic erythema and exfoliative dermatitis:

#### REPORT OF CASE

A man, aged 55, had previously visited the clinic in 1928. At the time the symptoms and signs on physical examination had been associated with an advanced exophthalmic goiter. The reading for the basal metabolic rate had been +83 per cent. A subtotal thyroidectomy had been performed. He had returned to the clinic three months later to report that he was enjoying excellent health. However, a moderately severe hypertension had been discovered. The value for the systolic blood pressure had been 205 mm. of mercury and that for the diastolic had been 135 mm. of mercury, in contrast to a very slight elevation in the value for the blood pressure prior to the thyroidectomy.

The patient was next observed at the clinic on May 19, 1936. His health had remained good until July 1934, when he had suffered from a cerebral thrombosis which had resulted in a right hemiparesis, from which he had rapidly recovered. During the two years before his last admission to the clinic, he had suffered from several moderately severe attacks of angina pectoris. On May 6, 1936, after such an attack, the value for the systolic blood pressure had been found by his physician to be 260 mm. of mercury. Two days later an elixir of sodium sulfocyanate had been prescribed in the dosage of three teaspoonfuls daily. He had continued to receive this medication for eleven days, at which time he had noticed a generalized eruption, "resembling the measles," over his body. Correspondence with the manufacturers of this elixir revealed that it contained 20 grains (1.3 Gm.) of sodium sulfocyanate in each fluidounce, so that the patient had received approximately

## Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

FRANKLIN C. BING, Secretary.

### DEXTROSE

#### Its Place in the Diet of Normal Adults

Sugars and foods rich in carbohydrates have been an important part of the diet from the earliest times. With the development of manufacturing processes, chemically pure sucrose, prepared usually from sugar cane or the sugar beet, gradually assumed a prominent place in the diet of the American people. Mendel<sup>1</sup> pointed out that the average per capita consumption of this chemically pure substance has changed from a relatively insignificant figure in prerevolutionary days to approximately one fifth of the average caloric intake in 1924. In recent years chemically pure dextrose, usually prepared from corn starch, has become available and is being promoted largely to replace part of the sucrose of the diet. Dextrose occurs naturally in many ordinary foods, in honey, in grape juice and other fruit juices, and in maple syrup. Dextrose is obtained as one of the products of the digestion of cane sugar and milk sugar, and it is the end product of the digestion of starches and of maltose. Within the body dextrose can be formed from glycogen, amino acids, the glycerol of fats, and probably from levulose and galactose. Thus it is apparent that there are a considerable number of sources of this important carbohydrate.

The wide occurrence of dextrose in foods, the vast literature of biochemical and physiologic investigations of this substance, and the claims made in advertising have led the Council to consider it desirable to publish a brief report on the significance of dextrose in the diet of the normal adult. It is the purpose of the present report to consider the evidence available on the nutritive properties of dextrose and to formulate for the guidance of interested persons claims which in the opinion of the Council are justified for this product.

An important property of dextrose is its sweetness as compared with other sugars. It is well known that certain sugars such as lactose from milk are not as sweet as ordinary cane sugar. In 1925 Biester, Wood and Wahlin<sup>2</sup> studied the relative sweetness of a number of pure sugars. They gave sucrose the arbitrary value of 100 and found that lactose was about one-sixth as sweet or had a value of 16. Levulose was observed to be almost twice as sweet as sucrose, its value being 173; dextrose on the same scale was recorded as 74. If sweetness is the consideration most desired, more dextrose must be used in a food mixture to produce the effect than either levulose or sucrose. Under certain conditions this property may be an advantage, under others a disadvantage. A number of physical and chemical properties limit the extent to which dextrose may be substituted for cane sugar; but these concern chiefly technical problems and are therefore outside the scope of the present report.

An enormous amount of experimental evidence has been accumulated on the subject of carbohydrate metabolism. It is well known that the digestion of carbohydrate results in the formation of three important monosaccharides—dextrose, levulose and galactose. Quantitatively dextrose is the most important, largely because starch, which yields dextrose on digestion, makes up the bulk of the carbohydrate of the diet. Deuel<sup>3</sup> has recently reviewed the available information on the metabolism of fructose and galactose. These two carbohydrates are absorbed into the portal blood and carried to the liver, where they are believed to be largely converted into dextrose and ultimately into liver glycogen. Some fructose and some galactose circulate in the systemic blood stream after the ingestion of these sugars or of carbohydrates which yield them during digestion, and there is considerable evidence that non-dextrose sugars may be oxidized or transformed to glycogen or fat.

Dextrose is the normal sugar of the blood. It is an important source of muscular energy. Although it has been called the fuel of muscular exercise, there is plenty of evidence that it is not the only fuel. Many physiologists have called dextrose the "physiologic" sugar. While this term is an expression of convenience and serves to emphasize to medical students the fact that sterile solutions of dextrose of proper concentration may be administered parenterally, yet as Deuel<sup>3</sup> has emphasized, other sugars are found in the body either temporarily following the ingestion of certain carbohydrates or permanently as pentoses, combined in the form of nucleic acids, which occur in the nuclei of all cells. Galactose is present as galactolipids in nervous tissue and it is also a constituent of lactose formed by the mammary glands. If dextrose is designated as the physiologic sugar, these other carbohydrates are certainly not pathologic. There are limitations, therefore, to the applicability of the slogan "dextrose, the physiologic sugar," especially when this term is loosely used by writers of advertising copy. Dextrose derived from dextrins, starch or protein certainly is no less valuable as a food than dextrose itself.

Because dextrose is absorbed as such and circulates unchanged in the blood stream, it has been supposed that it would be absorbed quickly and with no effort on the part of the body because it requires no enzymic process to make it suitable for absorption. Certainly dextrose is not as rapidly absorbed as the advertisements of some manufacturers would lead the uncritical reader to believe. Dextrose must be in solution and must reach the duodenum before it can be absorbed, since absorption does not take place from the stomach. Experimental evidence does not indicate that the rate of absorption of dextrose is significantly more rapid than that of many other carbohydrates of physiologic importance.

Maile and Scott<sup>4</sup> studied the relative rates of disappearance from the stomach of different sugars by means of roentgenograms taken after barium sulfate meals. They found in a few observations that sucrose left the stomach somewhat earlier than dextrose. However, their experiments were few in number, and the rapidity with which different solutions leave the stomach is not necessarily an index of the relative rates of absorption. By means of animal experiments, Cori<sup>5</sup> showed that, of the three important monosaccharides, galactose was absorbed somewhat more quickly than dextrose, and both of these sugars were absorbed much more quickly than levulose. It would seem that the pure monosaccharides which Cori fed might be absorbed more quickly when given in this form than when given in the form of polysaccharides, which require preliminary enzymic changes before absorption can take place. No extensive studies of the relative rates of digestion and absorption of disaccharides and polysaccharides have been made by the technic which Cori used.

In man the rate of absorption has also been studied by the determination of changes in the blood sugar. Following the administration of digestible carbohydrates, the blood sugar rises above the usual fasting level, as might be expected, but the rate and extent of rise is not the same for all carbohydrates. Folin and Berglund<sup>6</sup> showed that the administration of dextrose was followed by a rapid increase in the concentration of blood sugar but that other sugars such as levulose had little effect. Foster<sup>7</sup> likewise found that the ingestion of levulose resulted in but little increase in the blood sugar level. In such experiments the concentration of sugar in the blood is determined by the balance which exists between the rate at which sugars enter the blood from the gastro-intestinal canal and the rate of disappearance of the sugar from the blood. It is therefore difficult to interpret blood sugar curves on the basis of the rate of absorption from the gastro-intestinal tract only. It must be concluded from experimental evidence, however, that the blood sugar studies do show that dextrose is absorbed

sequelae of bacillary dysentery. Bargaen<sup>7</sup> holds that the disease, in common with chronic ulcerative colitis, probably results from several factors and micro-organisms, the most common of which is the streptococcus (Bargaen's diplostreptococcus).

Because the case reported here may contribute some information with respect to etiology, it seemed worthy of record. In this case the dysentery bacillus was present in cultures from urine obtained directly from the right kidney. Its identity was established by fermentation and agglutination. However, *Streptococcus haemolyticus* was present in cultures from fluid free in the peritoneal cavity and from a mesenteric lymph node. Thus there is presumptive evidence that the dysentery bacillus, present in the urine, had played a part in the inflammatory process in the ileum and that *Streptococcus haemolyticus*, present also in the urine and in the peritoneal cavity and a regional lymph node, had been a secondary if not a primary invader of the bowel wall.

#### REPORT OF CASE

J. R., a girl, aged 8 years, was admitted to the University of Nebraska Hospital Jan. 31, 1934. Her health had been excellent until thirty-one days previously, when a severe headache, a sore throat and generalized body pains suddenly developed and she vomited several times. Five days later generalized abdominal pain, a mild diarrhea, and a fever of 102 F. developed and she vomited many times. The vomitus on two occasions contained streaks of blood. No eruption developed. In five days, ten days after the onset, she returned to school but continued to complain of generalized abdominal pain and fatigue. For two weeks she attended school periodically. The pain gradually shifted to the lower half of the abdomen and twenty-four hours before admission she became acutely ill. The pain became more severe and colicky in character, the temperature rose to 102 F., she again vomited several times and a diarrhea developed.

The family and past histories were essentially negative.

She was well developed and nourished, despite considerable loss of weight.

The head, neck, heart and lungs presented no abnormality. The abdomen was moderately distended and tender throughout but was acutely tender immediately below and to the right of the umbilicus, where a mass was palpable. This mass appeared to be approximately the size of a large orange and was situated in the midline below the umbilicus, with the major portion on the right side. It was slightly but definitely movable, somewhat irregular in contour, tender and firm but not hard. These observations were confirmed by bimanual rectal examination, which also demonstrated the pelvic organs to be normal and the mass to be above the true pelvis.

The back and the extremities and the reflexes were normal.

Except for an occasional white and red blood cell the urine on several examinations was normal. Examination of the blood revealed the Wassermann reaction negative, hemoglobin 86 per cent (Sahli), red blood cells 4,340,000 and white blood cells 29,600, with staff polymorphonuclears 10 per cent, segmented polymorphonuclears 69 per cent and lymphocytes 21 per cent. The serum did not agglutinate *Bacillus typhosus*, *Bacillus paratyphosus* A and B, and *Brucella melitensis*. Two blood cultures gave no growth. Three stools contained undigested food and much mucus but no blood, ova, cysts, amebae or abnormal micro-organisms. Cultures of three stools yielded only bacteria that normally inhabit the bowel.

Roentgenograms of the chest, abdomen and urinary tract gave the following information: Intravenous pyelography showed no abnormality, the lung fields and pleural sacs were normal, and the heart was not enlarged. The gas-filled, distended loops of small bowel appeared separated as by fluid, and in the right iliac fossa just mesial to the cecum there was an area of increased density measuring 7 by 5 cm., suggesting a pericecal mass which under the fluoroscope was movable. With a barium sulfate enema the colon filled normally and no abnormality was found. The previously described mass did not appear to be connected with the cecum. Proctoscopic examination revealed no abnormality of the anal canal, rectum or lower sigmoid.

On admission the temperature was 103 F., the pulse 120 and the respiration rate 30. These rapidly subsided and were normal until the seventh day, when suddenly they recurred, as did the pain in the lower part of the abdomen and the vomiting.

The mass had remained unchanged. It was believed that it was not an appendiceal abscess because it was irregularly shaped and slightly movable (not fixed).

An exploratory operation revealed the following changes: There was considerable slightly turbid free fluid throughout the abdomen. Cultures of this were taken. Except for the terminal 8 inches, the small bowel was moderately distended. The great omentum was very thick, mildly injected and edematous. The walls of the cecum and of the terminal 8 inches of the ileum were moderately injected, spotted with petechiae, covered in areas with fibrinous exudate, edematous, rigid, and several times normal thickness to palpation. They were firm and elastic but not hard. The lumen of the ileum did not appear to be obstructed, gas passing freely through it. The mesenteries of both the ileum and the cecum were approximately 2 inches thick and felt brawny. They contained many large lymph nodes, one of which was excised for both pathologic and bacteriologic examinations. Except for a thickened and slightly edematous wall, the appendix appeared to be normal. It was removed and the peritoneal cavity was closed without drainage. A Penrose wick was placed in the abdominal wall down to the peritoneum. These observations seemed consistent with those reported by Crohn and his associates, so a provisional post-operative diagnosis of regional ileitis was made.

Cultures from both the peritoneal fluid and the mesenteric lymph node yielded *Streptococcus haemolyticus*. Microscopically the appendix was essentially normal and the lymph gland edematous with endothelial hyperplasia and with the presence of some foreign body giant cells.

The immediate postoperative convalescence was rather stormy and complicated by a wound infection, cultures from which yielded *Streptococcus haemolyticus*.

A few days after operation there appeared in the urine albumin, casts and many red and white blood cells, and, since these persisted for weeks after the patient's general condition was much improved, a cystoscopic examination was made by Dr. Edwin Davis, who reported that the urethra and bladder were normal, with no ureteral obstruction on either side. Plain films were negative; each kidney functioned normally; pyelograms were normal on either side.

The bacteriologic report of urine obtained through ureteral catheters was as follows: Urine from the left kidney contained a few white blood cells and hyaline and granular casts. Smear revealed gram-negative bacilli and gram-negative cocci; culture yielded *Bacillus coli*, *Bacillus mucosus-capsulatus*, *Bacillus pyocyaneus* and no tubercle bacilli. Analysis of urine from the right kidney gave identical results with the addition of *Staphylococcus aureus* and dysentery bacilli.

The wounds gradually healed, the mass slowly disappeared, and the patient was discharged, apparently well, sixty-six days after operation and has remained perfectly well to the present, now two years following operation.

1436 Medical Arts Building.

#### THROMBO-ANGIITIS OBLITERANS AND ADDISON'S DISEASE IN THE SAME PATIENT

SAMUEL SILBERT, M.D., NEW YORK

Since there is no record in medical literature of the occurrence of thrombo-angiitis obliterans and Addison's disease in the same patient, the following case is of unique interest:

H. G., a white youth, aged 20 years, seen in April 1935, stated that he was in excellent health until the summer of 1934, when he began to complain of pain in the toes of the left foot. This was thought to be due to a weak metatarsal arch. About two months later he first noticed pain in the left calf on walking and then found that he could not walk more than three blocks without stopping to rest. In December 1934 he observed that the left great toe became blue whenever it was put in warm water. In January 1935 ulceration developed in this toe and his physician applied a tannic acid dressing, following which gangrene of the entire toe developed. The toe was then amputated. A severe infection on the plantar surface of the foot proximal to the stump developed and was incised. The loose head of the first metatarsal bone was removed.

He used to smoke twenty cigarettes a day but stopped smoking in December 1934. His weight was 185 pounds (84 Kg.) in 1933. Between this time and December 1934 his weight went

## HOSPITAL AIR CONDITIONING

Complete air conditioning of a hospital would seem to involve large capital expenditures, depreciation and running expense which do not seem justified by the facts now known. Yaglou<sup>1</sup> has recently discussed in detail the problem of air conditioning as it applies to hospitals. At present it concerns principally nurseries for premature infants, anesthesia and operating rooms, oxygen therapy chambers, heat therapy rooms or cabinets and wards for allergic patients. The optimal air conditions, he says, for the growth and development of premature infants have been determined by using four valid criteria; namely, stability of body temperature, gain in weight, incidence of digestive syndromes and mortality. Comparative observations of premature infants in conditioned and unconditioned wards demonstrated conclusively the favorable effect of conditioning on stabilization of body temperature. The favorable effect apparently resulted from better control of temperature, superior ventilation methods, suitable provision for cooling the room in warm weather and the comparatively high humidity that prevailed. The optimal conditions for minimizing initial loss of body weight and shortening the period of recovery were obtained in conditioned nurseries with high relative humidity. Similarly, maximum gain in body weight after the first week of life occurred in the conditioned nurseries under high humidity in infants weighing less than five pounds. The incidence and severity of digestive syndromes with diarrhea, persistent vomiting, diminishing gains or loss of body weight and other untoward symptoms were generally twice as high under low than under high humidity. Finally, the mortality of premature infants was found to be greatly affected by humidity, achieving its lowest rate in conditioned nurseries under a high humidity of 65 per cent or more.

Air conditioning in operating rooms is mainly concerned with the welfare of the patient, the comfort and efficiency of the surgeon and his personnel and the safety of the whole procedure. There is complete

unanimity among all workers as to the effectiveness of high humidity on the prevention of accumulation of static; this is therefore an important measure of safety where explosive gases are used. The problem of operating room temperature is a difficult one and not much is known concerning the optimal air conditions necessary to maintain a normal body temperature under the influence of anesthesia and during the immediate post-operative period. What evidence there is, however, points to the desirability of maintaining reasonably cool conditions in the operating room for both patient and operating personnel.

There is a real advantage, the author believes, in the oxygen chamber over the oxygen tent when this method of therapy is indicated. A patient in a chamber receives unhampered medical and nursing care, and the oxygen concentration, the temperature and the humidity can be adequately controlled at any desired level. The chief disadvantages are high initial and operating costs. Since the temperature and humidity requirements in oxygen therapy depend primarily on the physical condition of the patient and secondarily on the type of disease, the ease of varying these factors in oxygen chambers is a matter of considerable import. In pneumonia, for example, the range of satisfactory temperatures and humidity is placed between 60 and 75 F., with from 20 to 50 per cent relative humidity. In this disease the consensus seems to favor a low humidity. While the criteria for air conditioning in fever therapy are not yet definitely established, the author expresses the opinion that water saturated or nearly saturated air of comparatively low temperature would probably prove more suitable for the production and maintenance of fever when used as therapy than the hot dry air now employed in some machines.

The use of air conditioned wards in the treatment of many allergic disorders has found considerable vogue. There is evidence that thermal factors are important in the precipitation of allergic attacks. Many factors appear to precipitate attacks, but the most potent appears to be a sudden temperature change, which may be practically eliminated by air conditioning. There are also many persons who cannot be effectively desensitized to allergens but who can obtain varying degrees of relief from filtration of air borne antigens. It appears, in fact, that the chief remedial factor in the treatment by conditioned air is the filtration of pollen. This effect can be obtained sometimes by simple filtration without air cooling. However, comfortable temperatures between 75 and 82 F. in warm weather and a relative humidity well below 50 per cent appear to be beneficial and desirable.

Enough preliminary work has now been done apparently to indicate the lines along which air conditioning should be introduced into hospitals. Before embarking on any program of air conditioning, Yaglou's report deserves the careful study of all those hospitals now or soon to be in a position to install additional equipment.

# A SIMPLIFIED METHOD OF TRANSFUSING CITRATED BLOOD

ROBERT R. BATES, M.D., CHICAGO

This method of transfusing blood is so simple that it is now preferred by the transfusion service at Passavant Memorial Hospital. No claim for originality in the separate features is made. The system is completely closed and sterilized in advance of need, thus obviating the necessity of an operating room.

A liter Florence flask is fitted with a two-hole rubber stopper through which a long U tube reaching to the bottom conducts the donor's blood when the flask is upright but acts as an air vent when the flask is inverted to discharge the blood. The other hole in the stopper admits a short glass Y tube, one arm of which connects to a detachable Potain aspirator providing suction when drawing the blood. The other arm of the Y (conducting blood to the recipient after the bottle is inverted) is equipped with a drip view and 3 feet of rubber tubing terminating in a small side arm intravenous syringe. Pinch clamps on each side of the Y, a gauze filter on coiled wire in the neck of the flask, and glass covers over the needles complete the apparatus.

Apparatus for a simplified method of transfusing citrated blood.

A nurse in sterile gown and gloves assembles the previously autoclaved parts into a unit, which is then laid aside ready for future use. The assembly includes placing 60 cc. of 2.5 per cent sodium citrate solution in the flask and inserting the filter and the stopper with the attached tubing. Finally the No. 16 donor's needle and the No. 18 recipient's needle are fitted with glass covers and the unit is then placed upright in a sterile bag.

The preparation of either donor or recipient with iodine and alcohol and tourniquet is as simple as drawing blood for a Wassermann test. Strong suction should not be used in drawing the blood; the flask should be agitated gently and when the desired amount of blood is drawn (up to 600 cc.) the donor's needle and tubing are immediately detached and washed. The rate of flow into the recipient may be increased by forcing air into the U tube with the Potain aspirator, but this procedure is rarely necessary. Hot water bottles placed about the flask and against the exit tubing insure warm blood for the recipient.

303 East Chicago Avenue.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—Ed.

#### THE THERAPY OF PARASITIC DERMATOSES

IN COLLABORATION WITH THEODORE CORNBLEET, M.D.

The meaning of the term "parasitic dermatoses" is restricted here to skin infestation with animal parasites, the term infection being employed for invasion of the skin by bacteria. In clinics dealing with the less fortunate members of society, animal parasites account for nearly 10 per cent of dermatologic cases.

In contrast to the bacterial diseases in which immunity develops and which are therefore self limiting, the parasitic disorders last as long as the parasites are present. It is true, however, that persons exposed to skin parasites for a long time become so accustomed to them that they seem bothered but little by them, while those newly infested suffer a great deal.

#### PEDICULOSIS

There are three types of infestation, depending on the type of parasite. These are head louse, body louse and pubic louse.

**HEAD LOUSE INFESTATION.**—*Diagnosis.*—Itching of the scalp, especially in children, possibly accompanied by a pustular eruption in the occipital region, should always lead to a search for pediculi and their ova ("nits"), which latter are attached in a characteristic acute angle to the hair shaft. The occiput and the region behind the ears are the most heavily infested. The occipital glands are frequently enlarged and they may suppurate. In extreme cases the hair may be matted together by dried exudate of an offensive odor.

*Treatment.*—Preparatory: Clipping the hair facilitates the treatment but it is not necessary and is certainly inexcusable in girls and women, unless the hair is so matted that it is impossible to apply the necessary remedies.

**Killing of the Parasites:** (a) Mercurial lotion. Most cleanly and hence generally best is the thorough sponging into the scalp and hair of a 1:500 solution of Mercury Bichloride in Diluted Alcohol twice daily for several days in succession. The chief disadvantage of this lotion is that it produces a burning sensation if the surface of the skin is damaged. A more dilute solution should then be used. (b) Oiling the scalp. While lice cannot be drowned in water, they can be drowned in oil. The thorough application of a thick layer of petrolatum suffices. The head is covered with a bathing cap or a suitably folded towel, which is left on over night. The petrolatum is then removed as thoroughly as possible by the use of sweet oil, after which the scalp is thoroughly washed with soap and hot water. (c) Benzene (5 per cent) petrolatum. Adding as many drops of benzene as there are grams of petrolatum facilitates its introduction into the respiratory apparatus of the para-

In the second table is shown for the same classes the number who graduated from a class A school and the percentage of these graduates now known to be practicing within and out of the state. From all the schools more than 25 per cent are found to be practicing outside the state and of six schools more than half of those graduated are known to be practicing outside the state.

In a school with a small student body, satisfactory educational standards can be maintained only with a

large expenditure for each student. So far as the state supported schools are concerned, better results could be obtained for less cost if a certain number of scholarships were annually provided open to bona fide residents of the state on a competitive basis. If thought necessary, it might even be stipulated that those to whom scholarships were awarded would return to practice within the state for at least three years.

SURVEY OF CHRONIC DISEASES

Results will apparently soon be available in the survey of chronic diseases inaugurated by the United States Public Health Service Oct. 1, 1935.<sup>1</sup> Field work of the survey was closed June 30, 1936. October 1 recording and card punching of the data gathered were about 50 per cent complete for the inventory as a whole. The chronic and disabling illness study comprises 867,000 family schedules, representing some three million persons. It covers a population from a third larger to a hundred times larger than that reported in previous surveys of comparable character. Among the previous surveys are the health and depression studies made by the U. S. Public Health Service in 1931 and 1933, covering 6,686 families and 28,959 persons. The study by the Committee on the Costs of Medical Care covered only 8,758 families representing 39,183 persons, and a similar survey by the Metropolitan Life Insurance Company in 1915 covered 637,038 policyholders and their families.

The survey of chronic diseases was conducted with the help of Works Progress Administration relief workers centering around a central office in Detroit. Approximately 1,300 persons are now at work on this survey. The first steps were house-to-house enumera-

tion. The field work of the survey was completed in April 1936 and was rapidly followed by completion of other related surveys such as communicable disease study, occupational morbidity and mortality study, the hearing survey and health facilities survey. The states included in the inventory had spent within their territory \$2,200,000 for enumeration activity, employing as high as 5,000 relief workers at one time.

The survey was conducted by asking persons in their homes about the presence of various health conditions, particularly chronic diseases. No diagnosis from a lay person was accepted and the lay enumerators were instructed to make no attempt at diagnosis. They simply enumerated the statements made to them. These were referred to physicians, who were asked to confirm the diagnosis. This question had been discussed previously with representatives of the American Medical Association and between an assistant surgeon general and the American Medical Association Board of Trustees. It was felt that many physicians might decline to give this information. It appears from the report of the survey now published that in most instances physicians with the permission of their patients confirmed the diagnosis or gave such information as resulted in correction of erroneous impressions which might have been gathered from a survey without medical confirmation.

The study is now in the punch card and sorting stage, but it is expected that before long there will be material ready for publication. The city that has been selected for early completion of the study is Grand Rapids, Mich. As these studies are published they will undoubtedly be of great interest to physicians who have contributed so liberally of their cooperation to make this study possible. The great care exercised in the preliminary preparations for this study and the high degree of public and medical cooperation that seems to have been achieved lend color to the hope that this first great and comprehensive study of disease conditions in the United States will be as accurate as it is comprehensive.

Current Comment

INSULIN SHOCK TREATMENT FOR SCHIZOPHRENIA

The amazing results already reported in some cases in which the insulin shock treatment has been applied in schizophrenia have resulted naturally in a certain amount of premature enthusiasm in relationship to the use of the method. It has been widely exploited in the press with the statement that it constitutes a cure for what has formerly been considered an incurable disease. As a result, the Committee on Public Education of the American Psychiatric Association has considered it worth while to issue a public statement on the present status of this new method. The statement comes with the approval of all the members of the

1. Health Officer 1: 333 (Jan.) 1937.

penis or in women the breasts and nipples. Otherwise lesions appear thickest on the dorsa of the webs of the fingers and sides of the fingers and on the flexor surface of the wrists and elbows, the anterior axillary fold, the ankles and the buttocks. Any other area may be involved. The number of lesions may be great in the unhygienic, among whom scabies is most characteristic. They are scanty in the cleanly, in whom diagnosis is difficult and may have to be made by exclusion or because of the itching. It is of aid in these ill defined cases to find burrows and it is diagnostic to extract from these minute tracts the causative animalcule, the acarus of scabies. Experience makes one adept at piercing the small grayish speck at the blind end of the burrow and bringing up on the tip of the needle or blade the clinging organism recognizable under the low power microscope.

**Treatment.**—All clothing that has been in contact with the skin during the course of the disease must be boiled, laundered or dry cleaned (which means a thorough immersion in naphtha). The patient should take a prolonged warm bath, thoroughly scrubbing with soap and brush. After drying the skin the remedy is applied to the entire skin below the clavicles. Sulfur ointment, preferably diluted (prescription 4), is to be used night and morning for a total of six times. Then

**PRESCRIPTION 4.—Diluted Sulfur Ointment**

R	Sulfur ointment .....	30.00 Gm.
	Ointment .....	30.00 Gm.
M.	Label: Apply to entire body below collar bones. (For scabies.)	

the bath is repeated and the clothes worn during the treatment should be boiled, laundered or dry cleaned. The "clean up" is the most important part of the treatment and also the most difficult to get carried out thoroughly, as well as the most expensive. For children, one-half or one-fourth the strength of the ointment used for adults should be prescribed. For those who have an idiosyncrasy against sulfur, 5 or 10 per cent betanaphthol ointment (prescription 5) should be resorted to. "One day cures," such as the Danish treatment, are apt to be too irritative.

**PRESCRIPTION 5.—Betanaphthol Ointment**

R	Betanaphthol .....	0.15 Gm.
	Ointment .....	30.00 Gm.
M.	Label: Apply to entire body below collar bones. (For scabies.)	

Continuance of the itching means (a) that the treatment was not thorough enough, (b) reinfestation from contacts, (c) residual irritation of the skin, possibly aggravated by the treatment, or (d) habit formation.

(a) To exclude the first possibility, one may repeat the treatment, which should always suffice.

(b) Infested contacts must be eliminated by treatment of these, or otherwise.

**PRESCRIPTION 6.—Borated Cold Cream**

R	Boric acid .....	3.00 Gm.
	Rose water ointment.....	30.00 Gm.
M.	Label: Apply locally. (To soothe and soften.)	

**PRESCRIPTION 7.—Diluted Ammoniated Mercury Ointment**

R	Ammoniated mercury ointment.....	15.00 Gm.
	Ointment .....	15.00 Gm.
M.	Label: Apply to lesions. (For pus infestation of skin.)	

(c) Residual irritation requires that the skin be soothed by Calamine Lotion or other bland application, or by 10 per cent borated cold cream (prescription 6) if it is excessively dry. If there is much trauma or if there are many raw areas from wild scratching, these should be cared for even before instituting measures for the scabies itself. Colloid baths and Calamine Lotion or Liniment help to prepare a badly scratched and traumatized skin for the more specific and irritating

scabies ointment. For pus infections, half strength Ammoniated Mercury Ointment (prescription 7) may be used after sponging with Mercury Bichloride Solution to remove the crusts.

(d) Habit requires psychotherapy, possibly plus Calamine Lotion as a placebo (see Pruritus).

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

**ICHTHAMMOL.**—Bitumen Sulphonatum, N. F. V.—Ammonium Ichthosulfonate.—"Ichthammol is obtained by the destructive distillation of certain bituminous schists, sulfonating the distillate, and neutralizing the product with ammonia." N. F.

For standards see the National Formulary under Ichthammol.

**Actions and Uses.**—See general article, Sulfoichthyolate Preparations and Substitutes, New and Nonofficial Remedies, 1936, p. 424.

**Ichthylol.**—A brand of Ichthammol, N. F.

Manufactured by the Ichthylol Company, Rahway, N. J. (Merck & Co., Inc., Rahway, N. J., distributor). No U. S. patent. U. S. trademark 62,603.

Ichthylol conforms to the standards of Ichthammol, N. F. VI, and in addition to the following standards: Dissolve 10 Gm. of ichthylol in 90 cc. of water, in a glass-stoppered cylinder and allow to remain undisturbed for twenty-four hours: no deposit forms. Transfer 0.5 to 1 Gm. of ichthylol accurately weighed to a Kjeldahl flask, dilute with 30 cc. of water, add 5 Gm. of potassium chlorate and 30 cc. of hydrochloric acid, evaporate the mixture to about 5 cc., add 25 cc. of hydrochloric acid, evaporate this solution to about 5 cc. again add 25 cc. of water; heat the solution to boiling, add 10 cc. of barium chloride solution, allow the mixture to stand twenty-four hours: the weight of the precipitated barium sulfate determined in the usual way will correspond to at least 10 per cent of total sulfur. If the ammonia contained in the ammonium sulfate as previously determined in ichthylol is calculated, and the result subtracted from the "total ammonia" as previously determined, the remainder will represent the ammonia combined with the organic sulfonic acids. If this value is multiplied by 1.88 the result will represent the sulfur present in the sulfonic acids in an oxidized state; i. e., the "sulfonic sulfur." If the sulfur contained in the ammonium sulfate as previously determined in ichthylol is calculated, and the result subtracted from the "total sulfur" as previously determined, the remainder will represent the sulfur present in the organic sulfonic acids contained in the substance. If the "sulfonic" sulfur in ichthylol as previously calculated is subtracted from the sulfur in the organic-sulfonic acids as previously calculated, the remainder will correspond to at least 5.5 per cent of "organic" ("sulfide") sulfur.

**RABIES VACCINE** (See New and Nonofficial Remedies, 1936, p. 376).

The Cutter Laboratories, Berkeley, Calif.

**Rabies Vaccine (Semple).**—Also marketed in packages of seven vials, each containing 1 cc.

**BACTERIAL VACCINE MADE FROM THE TYPHOID BACILLUS** (See New and Nonofficial Remedies, 1936, p. 401).

The Cutter Laboratories, Berkeley, Calif.

**Typhoid Prophylactic.**—Also marketed in bottles of 20 cc. containing 1,000 million killed typhoid bacilli per cubic centimeter.

**McKESSON'S HALIBUT LIVER OIL WITH VITAMIN D CONCENTRATE IN NEUTRAL OIL, 6 CC.**—Halibut liver oil with added natural vitamin D obtained from cod liver oil and other fish liver oils. It is assayed to have a potency of not less than 59,000 units (U. S. P.) of vitamin A per gram and not less than 1,000 units (U. S. P.) of vitamin D per gram.

Manufactured by the International Vitamin Corporation, New York (McKesson & Robbins, Inc., Bridgeport, Conn., distributor). The vitamin D concentrate used is made under U. S. patent No. 1,690,091.

**DIGITALIS** (See New and Nonofficial Remedies, 1936, p. 168).

**Tablets Digitalis Whole Leaf-Lederle, ¼ grain:** Each tablet contains ¼ cat unit.

**Tablets Digitalis Whole Leaf-Lederle, 1½ grains:** Each tablet contains 1 cat unit.

**Tablets Digitalis Whole Leaf-Lederle, 3 grains:** Each tablet contains 2 cat units.

Prepared by the Lederle Laboratories, Inc., Pearl River, New York.

were saved from subservience to the approved societies, and the intrusion into insurance practice of the evils of the old forms of contract practice was prevented. These results have been very far-reaching in their influence, for national health insurance practice not only affects a large proportion of the population but also sets the standard for other forms of contract practice.

The quotation here cited is not offered as an endorsement of the British system of health insurance. It is cited rather as an indication of the manner in which a united medical profession may express its wish to governmental authorities and legislative bodies. From present indications the medical profession in this country will, if necessity warrants, express its views with even greater unanimity than did our British confrères.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARKANSAS

**Two Day Graduate Course.**—The Arkansas Medical Society held its second two day course of graduate instruction at the University of Arkansas School of Medicine, Little Rock, January 13-14. Guest speakers included:

- Dr. Walter C. Alvarez, Rochester, Minn., Treatment of Diseases of the Digestive System.
- Dr. Curtice Rosser, professor of proctology, Baylor University College of Medicine, Dallas, Texas, Diagnosis and Management of Common Rectal-Anal Conditions.
- Dr. Urban Maes, professor of surgery, Louisiana State University Medical Center, New Orleans, Symptoms, Diagnosis and Treatment of Gallbladder Diseases.

**Bills Introduced.**—S. 120 proposes that the state accept an offer from the city of Little Rock to convey to the state the Little Rock City Hospital, which hereafter is to be known as the Arkansas State Charity Hospital and is to provide free hospitalization and medical treatment for the indigent sick of the state. H. 248 proposes to prohibit the cultivation, preparation, possession or distribution of marihuana. The bill proposes, however, that it shall not be unlawful for any licensed pharmacist to possess marihuana for sale on the written prescription of a physician, osteopathic surgeon, dentist or veterinarian.

### CALIFORNIA

**Bills Introduced.**—S. 291 proposes, in the event a business and professions code is enacted by the fifty-second legislature, to repeal the act to prevent blindness from ophthalmia neonatorum, approved June 11, 1915, and to enact in its stead as article 3, chapter 1, division 11, of the proposed business and professions code an article proposing to make it the duty of any physician, midwife, nurse, maternity home or hospital, and any person or persons attendant on or assisting at childbirth in all cases in which the child develops ophthalmia neonatorum within two weeks after its birth, to report the case within twenty-four hours after knowledge to the appropriate local health officer. Senate Constitutional Amendment No. 5 proposes to authorize the governing body of any city, county or city and county (1) to establish a general hospital for the treatment of both indigents and persons able to pay and (2) to adopt rules and regulations, among other things, with respect to the rate or fees to be charged nonindigent patients. S. 314 proposes to authorize the superintendent of schools of each county to employ one or more nurses to supervise the health of pupils enrolled in the elementary schools and to perform such duties as may be prescribed by the county superintendent of schools. A. 871 proposes to exempt from the provisions of the state sales tax "the gross receipts from the sale of drugs of all kinds and character." A. 880 proposes to establish a business and professions code and to consolidate and revise the law regulating, among other things, the licensed professions and callings. The bill proposes to create a department of professional and vocational standards to be composed of the board of dental examiners, the board of medical examiners, the state board of optometry, the state board of pharmacy, the board of exam-

iners in veterinary medicine, and the board of accountancy. Each of the boards comprising the department is to exist as a separate unit and is to set standards, hold meetings and set dates thereof, prepare and conduct examinations, pass on applicants, conduct investigations of violations of laws under its jurisdiction, issue citations and hold hearings for the revocation of licenses, and impose penalties following such hearings. The department is to have possession and control of records, books, papers, offices, equipment, supplies, funds, appropriations, land and other property now or hereafter held for the benefit or use of any of the bodies comprising the department. The bill proposes to prohibit various designated types of frauds of medical records and to prohibit certain types of advertising, such as advertising with respect to venereal diseases, lost manhood, impotence, seminal emissions, self abuse, or medicine or means for producing or facilitating a miscarriage or abortion, or for the prevention of conception. A. 937 proposes to permit nonprofit corporations to establish, maintain and operate nonprofit hospital service plans whereby hospital care is to be provided by said corporations to such of the public as become subscribers. No corporation is to be permitted to operate a nonprofit hospital service plan until it has procured the written consent of the commissioner of insurance. Apparently, corporations operating a hospital service plan on a profit basis or which, though operating such a plan on a nonprofit basis, conduct any business whatsoever on a profit basis are not to be able to qualify under this act. A. 1009 proposes to make it unlawful for any person to own, possess or operate any x-ray device or x-ray laboratory unless such device or such laboratory is operated under the direct supervision of a person licensed by the state board of health. Apparently only licentiates of the board of medical examiners, licensed osteopaths and licensed dentists are to be eligible for licensure by the board of health. However, nothing in the bill is to be construed to prohibit "the ownership, possession, maintenance or operation of x-ray devices used only as an incident to the lawful diagnosis or lawful treatment of persons by duly licensed physicians and surgeons, osteopaths, drugless practitioners, or dentists by means other than x-rays or x-ray devices or the taking of spinographs by duly licensed practitioners of chiropractic."

### COLORADO

**WPA Research Laboratory.**—In the news item describing a tuberculosis research laboratory recently built in Colorado Springs, appearing in THE JOURNAL, Dec. 26, 1936, page 2137, the letters PWA were inadvertently used instead of WPA.

**Society News.**—Dr. Jonas Curtis Lyter, St. Louis, discussed angina pectoris before a special meeting of the Medical Society of the City and County of Denver December 14.—Dr. Henry A. Buchtel, Rochester, Minn., discussed "The Use of Mandelic Acid" before the Pueblo County Medical Society in Pueblo, January 19.—Dr. Omer R. Gillett presented a paper before the El Paso County Medical Society, Colorado Springs, January 13, entitled "Some Sewage Problems Which May Be Related to Public Health."—At a meeting of the Northeast Colorado Medical Society in Sterling, January 15, Dr. Thad P. Sears, Denver, discussed arthritis.—The Crowley County Medical Society was addressed in Olney Springs, January 2, by Drs. George B. Stanley and William M. Desmond, both of Ordway, on "Streptococcic Infection of the Throat" and "Treatment of Influenza and Pneumonia" respectively.

### CONNECTICUT

**Library Named in Honor of Dr. Steiner.**—The library of the Hartford Medical Society has been named the Walter R. Steiner Medical Library in honor of Dr. Steiner, librarian since 1903. The change was made at a meeting January 4. A native of Maryland, Dr. Steiner graduated from Johns Hopkins University School of Medicine in 1898. He was president of the Medical Library Association from 1931 to 1933; secretary of the Connecticut State Medical Society from 1905 to 1912, chairman of its council, 1929-1933, and president, 1934-1935. He was president of the Hartford Medical Society in 1929 and of the American Clinical and Climatological Association, 1934-1935. Except for the sessions of 1926 and 1928, Dr. Steiner has been a member of the House of Delegates of the American Medical Association since 1919. The library of the Hartford Medical Society was begun sixty-two years ago and consists of about 20,000 volumes.

**Bills Introduced.**—H. 139 proposes to prohibit the sale, for household use, of any caustic potash, caustic soda or lye, oxalic acid or salt thereof, or any ammonia water in concentration of 5 per cent or more unless the container as retailed bears the word "poison" and a "statement instructing as to

rapidly from the intestinal tract, but whether it is more rapidly absorbed than other sugars is not entirely clear.

After it has been absorbed, dextrose is further converted by the normal person into glycogen and stored temporarily in the liver and muscle; it may be burned to yield ultimately carbon dioxide and water, with the production of heat and energy, or it may be transformed into fat and stored in the fat depots of the body. Under certain conditions some of it may even spill into the urine. The determination of the respiratory quotient has been used as a customary method of studying the relative rates of the oxidation of dextrose and other carbohydrates. This determination requires the measurement of the volume of carbon dioxide produced and the volume of oxygen consumed. The first figure divided by the second gives the value of the respiratory quotient. When dextrose is burned, the respiratory quotient is 1.0 because there are six molecules of carbon dioxide and six molecules of oxygen involved in the metabolism of one molecule of dextrose. When pure fat is burned, the respiratory quotient is about 0.70. It has been found that the respiratory quotient in the postabsorptive state is in the neighborhood of 0.80, which indicates that a mixture of fat and carbohydrate (and possibly protein) is being burned but that fat is the predominant fuel. If dextrose is given to a subject in this postabsorptive condition, the respiratory quotient is found to rise within sixty minutes to a value of about 0.90 to 0.95. When levulose is ingested, the respiratory quotient rises much more quickly; in about twenty minutes it has reached a value of 1.0. Figures above 1.0 also have been reported; these may be interpreted in at least two ways. High quotients, particularly those greater than unity, may mean that the carbohydrate is being converted into fat or it may mean that additional carbon dioxide is being eliminated because of a reduction in the bicarbonate content of the blood resulting from the formation of organic acids from the carbohydrate. Carpenter and Lee<sup>8</sup> attempted to overcome the latter objection by measuring what they call the alveolar respiratory quotient. With their technique they were able to corroborate the general observation that ingestion of levulose or sucrose is followed by a more rapid rise in the respiratory quotient than is observed after the ingestion of dextrose. The general conclusion is that levulose and sucrose are absorbed quickly (sucrose normally is converted first into levulose and dextrose) and oxidized quickly by the body. Studies of the respiratory quotient show that sucrose and levulose affect carbon dioxide production more quickly than does dextrose, but whether this means that these sugars are more rapidly absorbed and metabolized than dextrose is not clear.

Deuel<sup>9</sup> and his collaborators at the University of Southern California have made a number of interesting studies on the relative value of different carbohydrates in combating ketosis. Ketosis was produced usually by allowing the subjects to fast for several days or by the ingestion of high fat diets until the urine showed the presence of ketone bodies. Different carbohydrates were then administered and it was observed that galactose, levulose and sucrose were all superior to dextrose in combating the ketosis. They were also more effective than dextrose in causing a diminution in the amount of ketone bodies excreted in the urine and in reducing the urinary nitrogen excreted (the so-called nitrogen sparing action). Murlin and his collaborators<sup>10</sup> have recently reported somewhat different results. With dogs and human subjects they have found that the relative antiketogenic effect of different sugars varies with the method of producing ketosis, and even with the amount of sugar given.

As a result of the efforts of many physiologists and biochemists, a great deal has been learned about the fuel of mus-

cular exercise. In a recent review Dill<sup>11</sup> concluded that the fuel of light exercise is whatever may be available at the time when the body demands an extra source of energy. For exhaustive work, however, carbohydrates are important. In 1924 Levine, Gordon and Derick<sup>12</sup> reported some interesting observations on the effect of feeding dextrose to marathon runners. They observed that the exhaustion of the runner—after running from 14 to 18 miles—was correlated with low blood sugar values and they suggested the use of carbohydrate meals before severe athletic contests. The following year, 1925, they<sup>13</sup> reported experiments in which they provided runners with dextrose candies to be eaten during a marathon race. They reported an improvement in the condition at the end of the race of the runners who had eaten dextrose. Dill<sup>11</sup> pointed out that, while the feeding of carbohydrate and especially dextrose to an individual before an athletic contest may be a rational procedure from the engineering point of view, it has not received favor among athletes. The general feeling is that man is an animal subject to digestive upsets and should not be treated like a steam engine into which fuel is shoveled. A suggestion made by certain manufacturers of candies containing dextrose, that ingestion of their products will improve the athletic ability of the young man who eats it immediately prior to his events, is certainly not justified by adequate evidence. An interesting experiment along related lines has been made by Haggard and Greenberg.<sup>14</sup> These workers investigated the muscular efficiency of university persons and employees of a factory who were engaged in individual tasks on a piece work basis. The Yale investigators found that the efficiency with which a given task was performed was greatest when the blood sugar was high and the respiratory quotient near unity. This condition they were able to secure and to maintain for a longer period during the day by having the subjects eat mid-morning and midafternoon lunches. No studies of the effect of individual carbohydrates were made, and, in the opinion of the investigators, the beneficial results which they reported could be obtained by dividing the usual daily intake of food into five small meals instead of three large meals.

More recently Bjøe<sup>15</sup> determined the blood sugar concentration as part of an investigation into the physiology of severe exercise. He found that subjects who had previously subsisted on a high fat diet develop hypoglycemic symptoms during extraordinarily severe work much sooner than they did when subsisting on a high carbohydrate diet. The blood sugar could be quickly brought up to normal levels and the symptoms relieved by the administration either of dextrose or of sucrose by mouth.

#### SUMMARY AND ALLOWABLE CLAIMS

Dextrose is a sugar found in many natural products or incorporated in different fabricated food mixtures. It is also being produced in pure form in large quantities. Its sweetness is about 75 per cent of that of sucrose. Dextrose should not be termed the physiologic sugar, for such designation permits the connotation that dextrose is a preferred food; which is not compatible with known facts. Although dextrose requires no hydrolytic changes in the alimentary tract to prepare it for absorption, it is incorrect to state that it is instantly absorbed. Dextrose is well utilized as a food, but it possesses no practical advantages over many other carbohydrates in combating ketosis produced by either a high fat diet or by fasting, nor does dextrose itself have unique advantages when administered by mouth to prevent or relieve fatigue or to maintain muscular efficiency to a high degree. Dextrose is produced by the digestion of the most important dietary carbohydrate, starch. The evidence which indicates any superiority, under normal conditions, of dextrose ingested as the free sugar over dextrose ingested as the polysaccharide starch is not convincing.

health and preventive medicine and head of the department at Cornell University Medical College, New York. According to the *New York Times*, Dr. Smillie will represent Cornell in his new post in supervision of the health center in Kippis Bay, Yorkville, now being erected in cooperation with the New York City Department of Health. A native of Eaton, Colo., Dr. Smillie is 50 years of age. He graduated from Harvard University Medical School in 1912 and was an instructor from 1914 to 1916. He served as a staff member of the International Health Board of the Rockefeller Foundation from 1917 to 1927. Lent by the latter, he was director of the Instituto de Higiene, São Paulo, Brazil, from 1919 to 1921. Dr. Smillie is the author of "Public Health Administration in the United States."

**Bills Introduced.**—H. 1448, to amend the workmen's compensation act, proposes, in effect, apparently to deprive an injured worker of the right to select his own physician for the treatment of his industrial injuries. Specifically, the bill provides: "If the insurer provides a physician he shall forthwith notify the injured person's family doctor or other physician selected by the employee, which physician shall then be entitled to assume charge of the case, and the reasonable cost of said physician's services shall be paid by the insurer." H. 721 proposes that in proceedings to commit a person to an institution for the insane that person shall have the right, at his own expense, to be examined at reasonable times by physicians of his choice for the purpose of giving evidence at such hearing on the question of his mental condition. H. 791 proposes to create a commission, to consist of one member of the senate, three members of the house of representatives, and three persons to be appointed by the governor, to investigate and study (1) a method whereby medical and surgical services may be available to the indigent, to those who because of limited resources are unable unaided to meet the cost of serious illness and to those living in remote districts and where adequate medical services are not obtainable, and (2) the subject of medical education particularly in regard to discrimination as to the number of members of various racial groups permitted to study medicine, whether or not a fair opportunity to study in tax exempt hospitals is afforded to all properly qualified medical students, the advisability of establishing a grievance board to which an appeal may be made from dismissals of students in tax exempt medical schools and the relation between the American Medical Association and tax exempt medical schools with respect to medical education. This commission is to report the results of its investigation and its recommendations to the general court, together with drafts of suggested legislation, not later than the first Wednesday of December 1937. H. 892 proposes to require both parties to a prospective marriage, as a condition precedent to the obtaining of a license to wed, to present to the official authorized to issue a marriage license a statement, signed by a licensed physician, that neither party is infected with syphilis. The physician's statement must be accompanied by a record of a standard laboratory blood test made not more than forty days before the issuance of the marriage license. H. 1200, Appendix III, proposes to authorize the department of public health to supervise all bacteriological and clinical laboratories, to make the necessary rules for their regulation and conduct, and, in effect, to license such laboratories. The bill proposes to define a "bacteriological laboratory" as a place or establishment which is maintained "in whole or in part for the purpose of accepting for and subjecting to bacteriological study or analysis specimens of blood, sputum, urine, feces, or other fluids, secretions or excretions of the body of persons ill or suspected of being ill with a disease dangerous to the public health." "Clinical laboratory" is defined as a place or establishment maintained "for the purpose of accepting and subjecting to chemical, physical, biological or bacteriological study or analysis specimens of blood, sputum, urine, feces, or other fluids, secretions or excretions from the living body of persons not residing therein or in an institution of which said laboratory is an integral part." Nothing in the bill is to be construed to require a physician or a dentist, maintaining a laboratory personally or with the aid of paid assistants for the sole purpose of performing tests from specimens obtained from patients under the direct personal care of said physician or dentist, to be licensed by the department. H. 1200, Appendix 40, proposes to require a physician having charge at the birth of an infant born prematurely, other than in a hospital or institution equipped to care for such infants, and weighing less than five pounds, to notify the board of health of the city or town in which the infant was born within twenty-four hours after birth. The board of health on receiving notification must forthwith provide for the transportation of such infant to a hospital equipped to care for prematurely born infants unless in the opinion of the attending physician such removal is deemed inadvisable.

## MICHIGAN

**Bill Introduced.**—S. 60 proposes to grant to governmental hospitals and hospitals supported in whole or in part by private charity which have treated persons injured through the negligence of others, liens on all rights of action, suits, claims, counterclaims or demands accruing to the injured persons by reason of their injuries.

**Hospital News.**—The Interne Alumnae Association of Providence Hospital, Detroit, held its first annual winter clinic, January 5-9, at the Providence Hospital Nurses' Home. Dr. Walter Schiller of the University of Vienna was the guest lecturer.—The new McArthur Strange Hospital, Mount Pleasant, was opened recently.

**Scholarship in Honor of Dr. Parker.**—A scholarship will be established at the University of Michigan in honor of Dr. Walter R. Parker, emeritus professor of ophthalmology at the university's medical school, Ann Arbor. Funds will be provided through a gift of \$30,000 to the university under the will of the late Mrs. Parker. Dr. Parker, who still practices in Detroit, graduated from the University of Pennsylvania School of Medicine in 1891.

## MINNESOTA

**Committee on Syphilis Control.**—The council of the Minnesota State Medical Association has authorized the appointment of a committee on syphilis control. Dr. Samuel E. Sweitzer, Minneapolis, will be chairman.

**Bills Introduced.**—H. 401 and S. 433, to amend the workmen's compensation act, propose to add to the list of compensable occupational diseases, carbon monoxide gas poisoning. H. 442 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act.

**Imprisoned for Illegal Operation.**—Ethel Planque, also known as Ethel Benson, 52 years of age, was sentenced Dec. 21, 1936, by Judge Frank E. Reed, in the district court of Hennepin County, to a term of from one to fifteen years in the state reformatory for women at Shakopee. According to the Minnesota State Board of Medical Examiners, Mrs. Planque was indicted by the grand jury of Hennepin County, December 9, charged with manslaughter in the first degree, and on December 19 she was permitted to plead guilty to manslaughter in the second degree. The indictment was returned following the death of a 19 year old Minneapolis girl, following an abortion performed in Mrs. Planque's home in Hopkins. The defendant admitted that she had no medical training.

## MISSOURI

**Centennial Celebration in St. Louis.**—The St. Louis Medical Society will observe its one hundredth anniversary, March 22-23.

**Bill Introduced.**—S. 3 proposes to authorize the board of curators of the state university to establish a general hospital in connection with the school of medicine of the University of Missouri for the care and treatment of the indigent sick of the state.

**Society News.**—Dr. José Arcé, dean of the Faculty of Medical Science and professor of the surgical clinic, University of Buenos Aires, Argentina, addressed the St. Louis Medical Society, January 26, on "Packing Gauze Drainings After Total Pneumectomy," and Dr. Peter Heinbecker, "Factors Determining the Type of Surgery Applicable in Cases of Spastic Vascular Disease."—At a meeting of the Jackson County Medical Society, January 19, the following members of the Kansas City Pathological Society spoke: Drs. Ward W. Summerville, "Rheumatic Endocarditis and Pericarditis"; Morris S. Harless, "Aneurysm of the Aorta"; Cecil G. Leitch, "Hematological Studies."—Dr. Isidore Friesner, New York, lectured at the Oscar Johnson Institute, St. Louis, January 19, on the fundamentals of otolaryngology.

## NEVADA

**Bill Introduced.**—A. 15 proposes to authorize the sexual sterilization of certain socially inadequate inmates of state institutions.

## NEW HAMPSHIRE

**New Secretary of Registration Board.**—Dr. Fred E. Clow, Wolfeboro, was elected secretary-treasurer of the State Board of Registration in Medicine at a meeting in Concord, January 19. Dr. Clow succeeds the late Dr. Charles Duncan. Dr. Howard N. Kingsford, Hanover, was reelected president.

THE RISE OF MEDICAL JOURNALISM

In a series of articles<sup>1</sup> in current issues of the *London Lancet* a chronicler traces the rise of medical journalism from the earliest times to the present. He suggests that medical journalism began with the votive offerings found in the temples of Aesculapius; these were essentially clinical notes and were thus the starting point of medical literature.

In the period called the Dark Ages the publication of medical material lapsed, although industrious scribes kept medicine alive through their records, which were stored away in the monasteries. Apparently the first definite medical journal to be published in Great Britain was the *Foreign Medical Review*, which ran for ten years at the end of the eighteenth century. That publication had slight support. It was based largely on materials published on the continent of Europe, which were abstracted. Then in 1781 the *London Medical Journal* was established, which also was devoted to extracts from foreign material. Other periodicals appeared at fairly frequent intervals until in 1823 the *London Lancet* made its first appearance. With this publication medical journalism assumed a new shape. The immediate popularity of the *Lancet* was apparently due to the fact that it became a voice for the profession and at the same time supplied the physician with medical information. Its first editor, Thomas Wakley, did what he could to publish exact reports of the lectures given in the hospitals and records of the cases presented. Lecturers in the clinics who were accustomed to being paid for what they had to say objected to this pirating of their material and its dissemination in a periodical. A polemic discussion resulted with a fine calling of names and an exchange of scurrilous insinuations. The scurrility was, of course, in the nature of the times.

In this series of articles the author next considers modern attempts to develop medical information in a manner suitable for a public audience. In Great Britain the General Medical Council has warned physicians that they "should not append their signatures to descriptions of treatment as, in the by and large, the advice given could not be generally useful. Not to accept this warning is to run the grave risk of professional status." Fortunately the admonition is administered by the General Medical Council with a considerable amount of discretion. As every one knows, it is easily determinable from reading an article or interview in the lay press whether it is justifiable or essentially a means of advertisement of its writer.

The writer of these interesting observations in the *London Lancet* is convinced that the thread of medical journalism is unbroken from the time of Hammurabi to the days of the motor car, and he has found the tracing of that thread a fascinating avocation. There is yet not available in any one place a comprehensive history of medical journalism with a real analysis of its effects

on the trends of medical thought, on the advancement of medical science or even on the dissemination of medical knowledge. In a recent conference of the editors of the various state medical journals a considerable portion of one evening was given over to a discussion as to the extent to which the editor of a medical periodical might exert leadership in medical affairs. A review of the history of medical publications indicates that in the case of Wakley at least, and quite certainly in the case of an editor with the record of Dr. George H. Simmons, it becomes possible for those who mold medical thought to exercise leadership in no indefinite manner. Those who bear the responsibility for the issuing of medical publications may well realize the great responsibility which is theirs, particularly in times of active evolution.

WHAT HAPPENS TO STUDENTS OF TWO  
YEAR MEDICAL SCHOOLS

Among our medical educational facilities are some schools, located for the most part in small communities, without clinical facilities, which offer only the first two years of the medical curriculum consisting of the pre-clinical sciences. It is frequently asserted that such schools are needed in their respective states to provide an opportunity, not otherwise procurable, for the boys and girls resident in these states to undertake the study of medicine. It is claimed also that those who have attended these schools will return after graduation to practice in the states in which their medical career was begun.

To test the validity of such statements, an analysis has been made of the birthplace and present location of all students who entered these incomplete schools in the

TABLE 1.—Birthplace of Students

School	Number Admitted	Per Cent Born In the State	Per Cent Born Out of State
A.....	215	55	45
B.....	78	5	95
C.....	141	89	11
D.....	169	73	27

I.....	113	84	16
J.....	254	53	47

years 1925-1928. These classes were chosen because all of them have had at least four years since graduation in which to complete their internship and to become established in practice. In table 1 will be found, for each of the ten schools in the United States, the total number of students entering the first year class under the years under consideration, and the percentage who were born within, or outside of, the state in which the school is located. In one half of the schools more than a third, and in seven tenths more than a fourth of the students came from outside the state.

1. Grains and Scruples, *Lancet* 2:1358 (Dec. 5), 1422 (Dec. 12), 1485 (Dec. 19), 1542 (Dec. 26) 1936.

## Philadelphia

**Society News.**—The meeting of the Philadelphia County Medical Society, February 10, was devoted to a group of papers on "Etiology and Treatment of Edema," presented by Walter G. Karr, Ph.D., and Drs. Frederick William Sunderman, Charles L. Brown, Ralph M. Tyson and Seymour DeWitt Ludlum.—Dr. Leonard Colebrook, London, a member of the Medical Research Council of Great Britain, delivered a Nathan Hatfield Lecture before the College of Physicians of Philadelphia, February 3, on "The Control of Hemolytic Streptococcal Infection with Particular Reference to Puerperal Fever."—At a meeting of the Philadelphia Laryngological Society, February 2, the speakers were Drs. Thomas F. Furlong Jr., on "Preoperative and Postoperative Care of Mastoiditis"; Robert J. Hunter, "Methods of Interpreting Fork Tests in Decibels," and Douglas Macfarlan, "Ionization and Other Uses of Electricity in the Ear."—The Philadelphia Roentgen Ray Society and the Obstetrical Society of Philadelphia held a joint meeting February 4, at which the speakers were Drs. Benjamin H. Orndoff, Chicago, on "Diagnostic Uses of the X-Ray and the Biopsitome in a Study of the Corpus Uteri," and Paul A. Bishop, "X-Ray Pelvimetry."

## SOUTH DAKOTA

**Personal.**—Dr. Reginald H. Payne, Tripp, has been named director of a new health unit recently established in Hutchinson County, with headquarters at Tripp.—Dr. Clarence E. Sherwood, Madison, was elected president of the South Dakota Health Officers' Association at its annual meeting recently.

**Bill Introduced.**—H. 40 proposes, in effect, to compel all hospitals supported in whole or in part by public funds or exempted from taxation to permit all "physicians" to practice within their confines. A "physician" within the meaning of the bill is to be a person who has been "graduated from a school of practice in which the course of instruction shall have been for a period of not less than three years, or nine months each, including the following subjects: anatomy (with a full course in dissecting), histology, embryology, physiology, chemistry, toxicology, pathology, symptomology [sic], bacteriology, obstetrics, gynecology, psychology, mental and nervous diseases, skin and venereal diseases, general surgery, medical jurisprudence, hygiene and dietetics, public health and sanitation, with one year of clinical practice."

## TENNESSEE

**Bill Passed.**—S. 174 has passed the senate, proposing to make it unlawful for any person, other than a registered pharmacist, wholesale druggist, producer, or compounder, to sell, barter or possess cannabis or any compound, derivative or preparation thereof, except in accordance with the prescription of a licensed physician, dentist or veterinarian.

**State Association Sponsors Course in Obstetrics.**—A ten weeks course of lectures in obstetrics under the circuit plan is being presented to Tennessee physicians with Dr. Frank E. Whitacre, assistant professor of obstetrics and gynecology, University of Chicago School of Medicine of the Division of Biological Sciences, as the instructor under the auspices of the Tennessee State Medical Association. There are five towns in a circuit, with one session a week in each town. An hour's lecture and an hour for a clinic make up the instruction. Physicians may also consult Dr. Whitacre concerning their own cases as time permits. The fee is \$5, the greater part of the expense being borne by the state medical association, the Commonwealth Fund, the Vanderbilt University School of Medicine, Nashville, and the University of Tennessee School of Medicine, Memphis. Headquarters are in Memphis.

**Bills Introduced.**—S. 193 and H. 330 propose to create a board of naturopathic examiners and to regulate the practice of naturopathy. The bills provide that naturopathy "shall be construed as meaning the use and practice of Psychological and Material health methods and aids in purifying, cleansing and normalizing human tissues for the preservation or restoration of health according to the fundamental principles of anatomy, diagnosis, psychology and applied psychology. Naturopathic practice employs and sanctions the use among other agencies of Phytotherapy, Dietetics, Suggesto-therapy, Hydrotherapy, Zone-therapy, Bio-Chemistry, Massage, External Applications, Electro-therapy, Mechano-therapy, mechanical and electrical appliances, hygiene, first-aid, sanitation and Heliotherapy . . . provided, further, that the practitioners herein licensed shall not write or fill prescriptions calling for drugs." The bill further provides that such a practitioner shall not be permitted to use "X-ray Roentgen Ray machines for healing purposes, nor shall he follow the profession of a medical doctor."

## UTAH

**Bill Introduced.**—H. 86 proposes to authorize the trial court in actions for personal injuries to require the plaintiff to submit to a physical examination by one or more physicians designated by the court.

## WASHINGTON

**Bills Introduced.**—S. 103 proposes, as a condition precedent to the issuance of a license to marry, that each applicant therefor "produce and file . . . the certificate of a duly qualified physician, reciting that the applicant has submitted to a physical, mental and serological examination of a scope prescribed by the state department of health, and further certifying that the applicant is not feeble-minded, an imbecile, idiot, insane, a common drunkard, afflicted with pulmonary tuberculosis in its advanced stages, or any venereal disease." S. 134 proposes to repeal the law authorizing the sexual sterilization of certain socially inadequate persons and to enact in its stead a far-sweeping "eugenical sterilization law." S. 141 proposes to prohibit the possession, sale or distribution of amytal, luminal, veronal, barbital, acid diethylbarbituric, except on the prescription of a licensed physician, dentist or veterinarian. S. 140 proposes to require the proprietor or manager of a pharmacy to preserve for not less than five years the original of every prescription compounded or dispensed in the pharmacy and to permit the prescriptions to be inspected at all times by the prescriber, the board of pharmacy or any officer of the law.

## WYOMING

**Bills Introduced.**—H. 107 proposes to require governmental hospitals and all hospitals exempted, in whole or in part from taxation, to admit and care for "the patients of any regularly licensed physician, osteopath, chiropractic [sic], optometrist or dentist under the same terms and conditions as may be promulgated by the management of said hospital as the patients of any other regularly licensed physician, osteopath, chiropractic [sic], optometrist or dentist." H. 116 proposes to create a board of drugless therapeutic examiners and to regulate the practice of drugless therapy, which is defined as "any system of therapy that does not resort to the use of drugs, medicines, or operative surgery for the prevention, relief or cure of any disease."

## GENERAL

**Mid-South Graduate Assembly Postponed.**—On account of flood conditions, the Mid-South Post Graduate Medical Assembly which was to have been held in Memphis, Tenn., February 16-19, has been canceled.

**Conference on Occupational Disease.**—The Mid-West Conference on Occupational Disease will be held at the Hotel Statler, Detroit, May 3-7, under the auspices of the Detroit Department of Health, the Michigan State Medical Society, the Wayne County Medical Society and other interested agencies. The conference will be held in conjunction with the annual meeting of the American and Michigan associations of industrial physicians and surgeons.

**Exhibit of Scientific Photography.**—Monday February 15 is the closing date for entries in the international exhibit of scientific and applied photography sponsored by the Rochester (N. Y.) Technical Section of the Photographic Society of America (THE JOURNAL, January 16, p. 214). The exhibit, which will be on view from March 15 to April 3, will be divided in ten sections, including one on "Radiography and Medical Photography." Mr. C. B. Neblette, Rochester Athenaeum and Mechanics Institute, Rochester, N. Y., is secretary of the exhibit.

**Society News.**—Dr. Wingate Todd, Cleveland, was the guest speaker at the fall meeting of the Society for the Study of Asthma and Allied Conditions in New York in December. His subject was "The Value of Developmental Growth Studies in the Evaluation of Clinical Allergy." A round table conference was presented by the allergy clinic of Roosevelt Hospital.—Dr. John C. Wilson, Los Angeles, was chosen president-elect of the American Academy of Orthopedic Surgeons at the annual meeting in Cleveland, January 10-14, and Dr. Arthur Bruce Gill, Philadelphia, was installed as president. Dr. Philip Lewin, Chicago, was made vice president and Dr. Carl E. Badgley, Ann Arbor, Mich., secretary. The next meeting will be in Los Angeles, Jan. 15-19, 1938.

**Life Expectation Compared.**—The U. S. Bureau of the Census has recently issued figures comparing the life expectation of Negro and white men and women. Of 100,000 Negro males born alive, 91,268 will reach the second year of life as compared with 93,768 white male infants; 89,755 Negroes

committee<sup>1</sup> and also of the president of the American Psychiatric Association, Dr. C. Macfie Campbell, professor of psychiatry in Harvard University. "The impression that there never has been and is now," says the statement, "no treatment for dementia praecox, except through insulin therapy, is entirely erroneous. While dementia praecox has a less favorable outlook than many other forms of mental illness, much has been done and there are many forms of therapy each promising something. It is hoped, and may prove to be a fact, that the so-called insulin shock treatment for dementia praecox will find a useful place among the forms of treatment for dementia praecox, but its exact value has yet to be determined and it can be definitely stated that it is not a specific, nor by any means a cure for all cases of dementia praecox. It would be a source of regret should the insulin shock treatment be a means of holding out a false hope to the families of the tens of thousands of sufferers from dementia praecox when this hope most certainly cannot be widely realized with present day knowledge of insulin therapy. It is, however, at the present time receiving careful study in the New York and Massachusetts State Hospital systems, Bellevue Hospital, New York, and other scientific centers, but it should not be undertaken except by those adequately trained to meet the dangers connected with the treatment."

#### SYPHILIS IN A LARGE INDUSTRIAL ORGANIZATION

In a report on the incidence of syphilis in an industrial organization employing more than 36,800 persons, the Kahn precipitation test was used for diagnostic purposes. All new employees, according to Gehrmann,<sup>1</sup> and as many of the old employees as would voluntarily submit to the test, were examined by this means. Of the total 36,794 examined, 1,488, or about 4 per cent, were found positive. Positive results were checked with a second test in the central laboratory of the corporation and by Wassermann and Kahn tests done by an independent laboratory. With occasional exceptions it was the policy of the company to keep the results confidential between the central laboratory and the employee. Each employee with a positive reaction was carefully instructed concerning the nature of his condition and referred for treatment either to his physician or to a free clinic. Furthermore, each case was followed persistently by the staff of the medical division to insure adequate treatment. This follow-up information resulted in several expected and several surprising conclusions. Few of the employees with positive reactions refused to be treated. Some physicians, it is reported, attempted to charge fees that were not commensurate with the ability of the employee to handle. Physicians sometimes refused to treat the referred patients in spite of the positive test. In some instances when the attending

physician sent another blood specimen to a private or state laboratory and a negative report was returned the correctness of the diagnosis was denied. Many of the patients were discharged with insufficient treatment. A few patients were treated with pills alone. Although treatment at the free clinics was satisfactory, it was not always possible for the employees to conform to clinic hours and in some instances the clinics would not treat any patient who was employed. This study demonstrates the relatively high incidence of syphilis in at least one industry and the need for routine serologic examination. Furthermore, it is apparent that the cooperation of individual physicians in the treatment of syphilis should be improved if progress is to be made in combating the condition successfully.

#### MEDICAL ORGANIZATION AND SOCIAL SECURITY LEGISLATION

From time to time the Secretary of the American Medical Association has pointed out the importance of a completely united and well organized medical profession for the securing of proper medical representation. It is interesting to read in a recent review on "The Influence of the Association on Legislation"<sup>1</sup> a report of the extent to which the British Medical Association was able to influence considerations in that country of the National Health Insurance Bill. The consideration serves no less to establish the situation that confronted Great Britain at the time when the National Health Insurance Bill was first proposed in 1911. The review says:

The *cause célèbre* of the Association's Parliamentary work is, perhaps, the fight over the National Health Insurance Bill in 1911. Although the history of this conflict is well known, at least in its main outlines, its influence on the future of the profession was so vital and profound that it is well to reflect occasionally upon the full significance of the Association's success, and upon the degree of concerted action among medical practitioners that it was necessary for the Association to secure in order that the profession might achieve its victory.

It will be remembered that the Government did not consult the medical profession during the early stages of the preparation of the scheme; that the original proposals placed the control of medical benefit, including the appointment of doctors, in the hands of approved societies; and that no provision was made for the representation of the profession on any of the bodies entrusted with the administration of the system. Immediately after the introduction of the Bill the Association formulated its policy in its "Six Cardinal Points," which included free choice of doctor and patient, the administration of medical and maternity benefits by Insurance Committees, and the investment of medical committees with the control of professional discipline. The Association then began an intensive campaign to awaken the profession to the danger that threatened its independence. The response was immediate and whole-hearted, and the Association, supported by the signatures of 26,000 practitioners to a pledge to refuse service under the national health insurance scheme except on terms which accorded with its declared policy, and by the formal resignations of 33,000 doctors holding contract appointments with friendly societies, gained most of its points during the protracted negotiations with the Government.

The Association's achievement was of the highest importance to its own status and to the future of the profession. During the fight its authority was undisputed, and its firm refusal to allow any lay body to take part in the arrangement of professional terms of service has ensured to the profession direct access to Government authorities whenever negotiations on medical matters are needed. Medical practitioners themselves

1. Members of the committee include Dr. C. C. Burlingame, clinical professor of psychiatry at Yale University and psychiatrist in chief at the Neuropsychiatric Institute of the Hartford Retreat; Dr. Adolf Meyer, professor of psychiatry at Johns Hopkins University and director of the Phipps Clinic, Baltimore; Dr. William A. White, professor of psychiatry at George Washington University and superintendent, St. Elizabeth's Hospital, Washington, D. C.; Dr. Oscar Raeder, professor of psychiatry at Boston University and chief of the outpatient department of Boston Psychopathic Hospital, and Dr. Karl Bowman, professor of psychiatry at New York University and director of Bellevue Hospital.

1. Gehrmann, G. H.: Syphilis in a Large Industrial Organization, Pub. Health Rep. 17: 227 (Aug.) 1936.

1. The Influence of the Association on Legislation, Brit. M. J. Supplement, Jan. 23, 1937, p. 42.

This has been done under the advice of Mr. Stanley Morison, who was largely responsible for the change of the type face undertaken by the *Times* in the latter part of 1932. The main object is to help the reader and the reader's eyes. The type used for the first issue in 1937 is the product of some years of experiment in the offices of the *Times*, where it was subjected to severe tests. It gives a clear plain print, especially designed for easy reading when set up in columns and produced under newspaper conditions. It is bolder and more legible than any type previously used by the *Journal*. The types used for headings and cross-headings are based on the letter of the text fount, thus achieving unity throughout the pages—a feature lacking in many periodicals.

A striking change has been made in the cover, which is now gray with a scarlet device. A new feature is the list of "Principal Contents," which are for the first time displayed on the outside. This is claimed to be "a gain to all whose time is precious" and to "enable the reader to single out from other matter the subjects dealt with in original papers and special articles." The full table is in its usual place. Another new feature is the adoption of the Harvard system of giving references to scientific literature and the use, with slight modification, of the abbreviations of the World List of scientific periodicals.

## PARIS

(From Our Regular Correspondent)

Jan. 16, 1937.

### Some Social Insurance Statistics

Dr. Phillip Dally in the *Presse médicale*, Dec. 16, 1936, states that in certain countries like France, where state ownership is being rapidly extended to include a number of industries, it is not surprising to note that state medicine is the next objective. In this light, it is of interest to study the statistics of those countries in which sickness insurance is compulsory, as to whether such a law has been of benefit to the citizens in the form of a lower morbidity and mortality rate. A study of this question for the years 1911-1934 appears in the 1936 report of the Committee on Hygiene of the League of Nations. French statistics cannot be used for comparison because the social insurance law has been in effect only since 1930. South Africa, Australia, Canada, New Zealand, Norway and Holland had a mortality rate of 10 per thousand in 1914. Of these, obligatory sickness insurance existed only in Norway. The mortality rate in the United States was 11 per thousand, but this includes the high mortality rate of Negroes. If this were excluded, the rate in the United States, in which there is no sickness insurance, would be less than in those countries in which it is obligatory. Only one country, Chile, in South America, has compulsory sickness insurance. The mortality rate in Chile in 1934 was 26.8 per thousand, as compared to 11.8 per thousand in the republic of Argentina and 10 per thousand in Uruguay. If one studies the influence of sickness insurance on certain causes of death especially amenable to medical treatment, such as diphtheria, some interesting facts are brought out. In the United States and Canada, with the exception of New Orleans and Quebec, no city has a mortality rate from diphtheria above 6 per cent. In Germany and Great Britain, where sickness insurance is obligatory, the mortality rate of diphtheria is 11 per cent and 11.6 per cent, respectively, as compared to 5.2 per cent in Spain and 4.5 per cent in Australia and practically nothing in New Zealand. In none of these three last named countries is sickness insurance obligatory. Similar mortality rates hold true for pulmonary tuberculosis for those countries in which sickness insurance is compulsory compared to those in which it is not.

With regard to infant mortality, the rate for the countries in which sickness insurance is not obligatory is 61 per thousand for South Africa, 72 for Canada, 60 in the United States,

44 for Australia, 32 in New Zealand, 47 in Sweden, 46 for Switzerland and 43 for Holland. This compares favorably with the following countries, in which sickness insurance is obligatory: Germany 66 per thousand, England 59, Denmark 64 and certain cities such as Santiago (Chile), 244.

The conclusion to be drawn from this report, according to Dally, is that the morbidity and mortality rates are lower in the countries in which sickness insurance is not obligatory.

### The Odious "Patente" Tax

In an article entitled "The Odious 'Patente' Tax" in the Dec. 15, 1936, issue of the *Siècle médical*, the unfairness of this additional tax on all members of the liberal professions is complained of. In France, every physician and dentist is taxed by the city or county in which he lives, on his professional income after deductions for professional expenses. In addition there is a personal property tax based on the rent paid for an apartment or house. The "patente" is a third tax, levied on the members of all liberal professions and based on the rent paid for an office or on rental value of the rooms used for professional purposes, if such quarters constitute a portion of the apartment or house in which the physician or dentist, for example, lives. Only within the last few years has the government restricted the "patente" (or privilege) to the rent paid for an office or on the rental value of the rooms actually used as offices. Before this recent lightening of the tax burden, a physician or dentist had to pay the "patente" not only on the rooms used as offices but also on the rental value of his house or apartment if these were separately located, as well as a third "patente" on any suburban residence, even though not used for professional purposes. The medical and dental professions have protested in vain against the injustice of these three taxes on net earnings, on personal property and on the license or privilege to practice; i. e., the "patente." The author of the article in the *Siècle médical* states that the "patente" tax has become such an additional burden that many physicians and dentists will be obliged to close their offices. Although the "patente" was abolished in 1935 for space not used for professional purposes, this suppression has been followed by higher taxes for the rooms used for professional purposes. A letter from a practitioner in the south of France is quoted as complaining of a "patente" tax in 1935 of 8,500 francs (about \$425 at the present rate of exchange) based on a rent of 11,700 francs. For 1936 the "patente" tax has risen to 16,500 francs, although the rent of the offices has not been increased. Another correspondent states that his "patente" tax is 8,000 francs and his rent only 6,300 francs.

### Abuse of Free Medical Care by Physicians and Their Dependents

In the Dec. 13, 1936, *Concours médical* appears an article on the care of members of the medical profession, by one of the editors of the journal, Dr. Raphael Massart. The article is the second of a series on reflections on the practice of medicine. Massart states that both tradition and the code of ethics demand that medical care shall be given to physicians and their dependents without a thought of receiving any remuneration. This custom, which is one of the most noteworthy evidences of the solidarity of the medical profession, is unfortunately not always respected; hence the committees on ethical relations here are frequently called on to hear complaints of abuses of this privilege. Although the code of ethics imposes certain obligations on those who are called on to treat their professional brethren and their dependents, there are also certain duties incumbent on those who receive such free treatment. Every medical man hesitates to call on another to care for himself and his family because he appreciates the loss of time and the fact that in many an instance the recipient of such care cannot reciprocate directly or indirectly. The result is

treatment in case of accidental swallowing of or injury by such chemical." H. 17 proposes to forbid a licensed physician to disclose any information of a confidential character which he may have acquired in attending any patient in a professional capacity and which was necessary for him to serve the patient professionally. H. 329, to amend the state pure food and drug act, proposes that the term "drug," as used in that act, "shall include all medicines and preparations recognized in the United States Pharmacopeia or National Formulary for internal or external medicinal use, any substance or mixture of substances intended to be used for the cure, mitigation or prevention of disease of either man or animals, and any substance or mixture of substances of an antiseptic, tonic or toilet nature for internal or external use."

## DISTRICT OF COLUMBIA

**Medical Bills in Congress.**—*Change in Status:* H. R. 4113 has been reported to the House, proposing to issue a license to practice the healing art in the District of Columbia to Dr. Ralph Charles Stuart. *Bills Introduced:* S. 1224, introduced by Senator King, Utah, proposes to amend the optometry practice act in the District of Columbia so as to permit any individual, firm, partnership or corporation to maintain an optometric department in a mercantile establishment when such department is under the supervision, direction and management of a regularly licensed and registered optometrist. S. 1225, introduced by Senator King, Utah, proposes to provide for lunacy proceedings in the District of Columbia. H. R. 3891, introduced by Representative Quinn, Pennsylvania, proposes to regulate the practice of cosmetology in the District of Columbia. The word "cosmetology" is defined in the act to mean "any one or any combination of practices generally and usually, heretofore and hereafter, performed by, and known as the occupation of, beauty culturists, or cosmeticians, or cosmetologists, or hairdressers, or of any other person holding him or herself out as practicing cosmetology by whatever designation and within the meaning of this Act and in and upon whatever place or premises; and in particular 'cosmetology' shall be defined and shall include, but otherwise not be limited thereby, the following or any one or a combination of practices, to wit: arranging, dressing, styling, curling, waving, cleansing, cutting, singeing, bleaching, coloring, or similar work, upon the hair of any female person by any means, and with hands or mechanical or electrical apparatus or appliances, or by the use of cosmetic preparations, antiseptics, tonics, lotions, or creams, massaging, cleansing, stimulating, manipulating, exercising, beautifying, or similar work, the scalp, face, neck, arms, bust, or upper part of the body, or manicuring the nails of any person."

## GEORGIA

**Personal.**—Dr. Charles W. Reid, Pelham, has recently completed fifty years in the practice of medicine.—Dr. Thomas F. Abercrombie, director, state department of health, was awarded the honorary degree of doctor of science during the centennial celebration of Emory University, December 12.—Dr. Rufus F. Payne, Lebanon, Tenn., has been appointed health officer of Tift County; he formerly served in a similar capacity in Walker County.

**Bills Introduced.**—H. 84 proposes to authorize the board of regents of the university system of Georgia to establish and maintain in the University of Georgia, located at Augusta, a department for instruction in dental sciences and related subjects. H. 36 and S. 37 propose to grant to physicians, drugless practitioners, dentists, nurses and hospitals treating persons injured through the negligence of another, liens on any claims, moneys or things of value accruing to the injured persons because of their injuries. H. 78 proposes to authorize the department of public health to establish a standard for the organization, equipment and conduct of cancer units or departments in general hospitals in the state, to provide a plan for the care and treatment of indigent persons suffering from cancer, and to acquire such laboratories, hospitals or other property as is necessary to carry out the purpose of the act. The bill proposes to appropriate \$100,000 annually to enable the department of public health to carry out the provisions of the act. H. 179 proposes that a "regular physician or surgeon" shall not, without the consent of his patient, be examined in any civil action as to any information, or opinion based thereon, acquired in attending the patient, which was necessary to enable him to prescribe or act for the patient. S. Res. No. 9 proposes an amendment to the constitution to permit the general assembly to delegate to any county the right to levy a tax for the purpose of furnishing medical care and hospitalization for the indigent sick of the county.

## ILLINOIS

**Typhoid Carriers.**—Fifty-four new typhoid carriers were detected in Illinois during 1936. This brings the number of carriers under state supervision to 162, according to the Illinois Department of Health.

## Chicago

**Hospital News.**—The dedication of the new \$200,000 annex to the St. Francis Hospital will take place in May. Work was started last July. The present building of the hospital was constructed in 1923.—St. Elizabeth Hospital celebrated the fiftieth anniversary of its founding, Nov. 14-16, 1936.

**Society News.**—Dr. Frances A. Ford, Detroit, addressed the Chicago Council of Medical Women, February 5, on "The Contact of the Average Physician with the Problem of Cancer."—Dr. Alfred Adler of Vienna gave a lecture January 24, on "The Meaning of Neurosis." The lecture was under the auspices of the Chicago Association for the Study and Advancement of Individual Psychology.

**Personal.**—John McKinlay was elected president of the Presbyterian Hospital Association at its annual meeting, January 20, succeeding Alfred T. Carton, who resigned.—Dr. Harold J. Noyes, clinical associate of pediatrics, Rush Medical College, addressed the Cleveland Dental Society, February 1, on "Modern Dental Contributions to Medical Diagnosis." Dr. Noyes also has a degree in dentistry.—Dr. Anna M. Braunwarth observed her eightieth birthday January 11; she has completed fifty years in the practice of medicine.

## INDIANA

**Bill Introduced.**—H. 169 proposes to enact a "workmen's occupational disease act" and to make compensable any disablement arising from any occupational disease arising out of and in the course of the employment. The term "occupational disease" is defined to mean a disease arising out of and in the course of employment. A disease is to be deemed to arise out of the employment only if there is apparent to the rational mind, on consideration of all the circumstances, a direct causal connection between the conditions under which the work is performed and the occupational disease; if it can be seen to have followed as a natural incident of the work as a result of the exposure occasioned by the nature of the employment; if it can be fairly traced to the employment as the approximate cause, and if it does not come from the hazard to which workmen would have been equally exposed outside of the employment.

## IOWA

**Personal.**—Dr. Harold T. Werner has resigned as head of the Santa Fe Hospital, Fort Madison, and has moved to Paducah, Ky., where he will engage in practice.

**Bill Introduced.**—H. 59, to amend the chiropractic practice act, proposes to authorize the board of chiropractic examiners to license chiropractors to practice physical therapy provided such licentiates have pursued a course of training of at least 200 school hours in physical therapy in some recognized institution and shall pass an examination in physical therapy to be given by the board. The bill proposes also to permit chiropractors to practice in all state and public institutions and hospitals supported by public taxation and to permit chiropractors to examine applicants, to recommend admissions and releases, and make reports in connection with the admission of patients to all state or other public institutions.

## KANSAS

**Bill Introduced.**—S. 116 proposes to authorize the establishment and maintenance of a state pneumoconiosis and tuberculosis sanatorium in Cherokee County and to appropriate \$300,000 for the fiscal years ending June 30, 1937, and June 30, 1938, for the erection, equipment and maintenance of the sanatorium.

## MASSACHUSETTS

**Dr. Strong Lectures in London.**—Dr. Richard P. Strong, professor of tropical medicine, Harvard Medical School, Boston, delivered the first Chadwick Lecture of the Royal Society of Tropical Medicine and Hygiene, London, January 21. His subject was "Onchocerciasis in Central America and Africa." Dr. Strong was recently elected an honorary fellow of the society.

**Dr. Smillie Goes to Cornell.**—Dr. Wilson G. Smillie, professor of public health administration at Harvard School of Public Health since 1927, has been chosen professor of public

that for the population as a whole. The basis for this is always to be found in the lesser incidence of marriage. Since this depends on the inherited characters of the schizophrenic and not on external circumstances, it does not matter whether the onset of the disease is early or late. Among schizophrenic subjects there is also a reduced marital fertility. The different groups of schizophrenic subjects present individual peculiarities. The hebephrenic, for example, offer the lowest figure for marriages previous to the onset of the disease. On the other hand, those groups in which the illness manifests itself in circular insanity strangely enough resemble the manic-depressive patients in the incidence of marriage and fertility. This incidence prior to the onset of illness coincides with that of the average members of the population. In each generation some 10 per cent of schizophrenic subjects are the offspring of a diseased parent. Skälweit believes that this progeny would be reduced by about 33 per cent if every schizophrenic patient were to undergo sterilization on the first admission to a clinic. From the eugenic point of view early diagnosis may be of the utmost importance, as it may make possible an obliteration of the procreative function of the patient before the onset of the disease.

Dr. Reichardt has investigated the heritability of ozena at the Freiburg-in-Breisgau University Clinic for diseases of the nose and throat. Numerous observations lead him to conclude that the predisposition to this disease should be considered the prime factor. Reichardt examined not only the ozena patients of the clinic but their relatives as well. He found, like other investigators before him, that in many instances the disease may be observed to continue over several generations. He regards it as highly improbable that an infection is responsible for the disorder. Research on twins has demonstrated that ozena may be detected in one pair of enzygotic twins, whereas in another pair a manifest atrophic rhinitis may be established. The pathogenic predisposition is apparently inherited as a dominant character.

TABLE 3.—Empirical Hereditary Prognosis in the Cyclothymiac Group

	Manic-Depressive Insanity, per Cent	Psychopaths of the Cyclothymiac Circle, per Cent	Number of Adults Investigated
Children.....	24.4	18.4	298
Nephews and nieces.....	2.4	2.0	602

TABLE 4.—Differentiated Hereditary Prognosis for Children of Manic-Depressive Parents

	Probability of Affliction with Manic-Depressive Insanity, per Cent	Incidence of Psychopaths of the Cyclothymiac Group, per Cent
Both parents manic depressive.....	38.7	50.0
One parent manic depressive, the other a cyclothymiac psychopath .....	29.6	17.9
One parent manic depressive, the other normal .....	30.6	14.5

Other investigations carried on by Dr. Scheurlen at Tübingen concerned the heritability of pigmentary degeneration of the retina. Examination was made of 506 patients who presented retinitis pigmentosa. The relatives of these patients were likewise examined. An equal familial distribution of the disease was revealed besides indications of a predominantly recessive hereditary predisposition. Close consanguinity of parents played no decisive part in the manifestations of the affliction, where-

fore it is concluded that the entire population has been permeated for centuries with the pathologic gene (this last conclusion was made on the basis of investigations carried on in Württemberg). The number of cases in proportion to the total population at a given time has neither increased nor decreased in the course of the last fifty years.

	..	2	4	6

The family trees of ninety-four patients were studied; these showed a descendance of children and grandchildren who were all completely healthy (with the exception of a woman who had retinitis pigmentosa, whose two sons were similarly afflicted). The number of healthy phenotypes present in the descendance amounted to 237. Had these ninety-four patients been sterilized, the birth of only two children with inherited disease would have been prevented, but at the same time 237 healthy descendants would never have been born. Dr. Scheurlen adds that the goal of extermination of recessive hereditary diseases (in addition to the sterilization of diseased persons) will be attained only through the exclusion of the heterozygotes from the hereditary transmission.

Recently the Reichsgericht as supreme court of judicature has decided that a hereditary predisposition to a mental disease on the part of one marriage partner constitutes a legal ground for contesting the validity of a marriage even if during the existence of the marriage no mental disorder has been manifested. Nor is it of legal significance whether or not a psychotic manifestation may have been aggravated during the married state by uncongenial external circumstances or by the reprehensible conduct of the healthy spouse. The only important consideration in the eyes of the law is the establishment of a pathologic predisposition.

A man found guilty of an insult to a person of defective heredity was recently sentenced to two months' imprisonment. The complainant with the hereditary taint had previously undergone sterilization. The defendant was seated in a public house one day when this sterilized man approached and asked if he might sit at the same table, whereupon the defendant had turned him away with a brutal reference to his physical condition.

The National Health Bureau has initiated a sort of genetic census. As this project is incomplete, only makeshift classifications can be used as yet and the persons catalogued are roughly divided into the genetically inferior and the genetically superior. Criminality also is easily distinguishable. The

**Bills Introduced.**—H. 119 proposes to permit paupers, at the expense of the proper poor district, to obtain for themselves the services of any licensed practitioner of the healing art. H. 135 proposes that no person be required to submit to any form of vaccination or inoculation as a condition precedent to admission to any school, institution of learning or public institution, nor to the exercise of any right, performance of any duty or enjoyment of any privilege. The bill also proposes that any physician who vaccinates or inoculates a child without the written consent of its parents or an adult without the written consent of the adult be subject to a fine of \$100 or imprisonment for one year or both.

### NEW MEXICO

**Bills Introduced.**—S. 50 proposes to create the Carrie Tingley Crippled Children's Hospital to provide proper care and treatment for the crippled children of New Mexico and to make available therefor the building erected, furnished and equipped for such purpose by the federal government at Hot Springs, Sierra County. H. 19, to amend the uniform narcotic drug act, proposes to define "narcotic drug" so as to include cannabis. S. 1 proposes to create a board of naturopathic examiners and regulate the practice of naturopathy. A license to practice naturopathy is to entitle the holder thereof "to administer any and all natural and constructive remedies and treatment in human ailments as taught in standard and chartered naturopathic colleges, schools or universities . . . and to issue birth, health and death certificates." H. 41 proposes to forbid the issuance of marriage licenses unless there is filed with the officer authorized to issue such licenses a physician's certificate showing that both parties to the proposed marriage are free from syphilis. H. 44 proposes to authorize the sexual sterilization of certain socially inadequate inmates of state institutions.

### NEW YORK

**Bills Introduced.**—A. 299, to amend the law requiring the licensing of laboratories and other places in which live pathogenic germs are handled or cultivated, proposes to require such licensure from all places "where live pathogenic micro-organisms or viruses other than vaccine virus are handled or cultivated." The bill also proposes to prohibit all persons, other than licensed practitioners of medicine, dentistry or veterinary medicine or persons acting under the direct supervision of the licensed practitioners noted, to possess or cultivate live pathogenic micro-organisms or viruses other than vaccine viruses unless such persons have satisfied the state commissioner of health that such micro-organisms or viruses in their possession will not become a menace to the public health and unless they hold a permit issued to them by the state commissioner of health. The bill also proposes that all live pathogenic micro-organisms or viruses other than vaccine virus when given away or sold shall bear a label on the container showing the registration number of the distributor which has been issued by the state department of health for the handling of pathogenic micro-organisms or viruses, the name of the person obtaining the material and the destination of the pathogenic micro-organisms or viruses. A. 312 and S. 316 propose to prohibit a person from practicing as a clinical laboratory technician unless licensed by the education department. The bills define "clinical laboratory technicians" as persons who perform any technical laboratory procedures, including bacteriology, biochemistry, hematology, clinical pathology, immunology, parasitology, histology or tissue technic, or basal metabolism, which are used for the purpose of diagnosing, investigating or treating any disease, illness or infection. A. 335, to amend that section of the workmen's compensation act which requires an injured employee to submit to such physical examination as the industrial commissioner or the industrial board may require, proposes to strike out the provision that "such physician or physicians as the employee or carrier may select and pay for may participate in an examination if the employee or carrier so requests." A. 346 proposes to denominate the division of social hygiene in the department of health as the "division of syphilis control." A. 355 proposes to prohibit the issuance of a license to marry until there is presented to the clerk authorized to issue such a license "a statement or statements signed by a licensed physician that each person intending to be married has submitted to a Wassermann or Kahn or other similar standard laboratory blood test and that, in the opinion of such physician, the person is not infected with syphilis or in a stage of that disease that may become communicable and such statements shall be accompanied by a record of the standard laboratory blood tests made." A. 471 proposes to authorize courts to enjoin the unlicensed

practice of any profession or vocation for which a license or registration is required by law. A. 513 proposes to prohibit hospitals from permitting an employee to work more than eight consecutive hours in any twenty-four hours or more than forty-eight hours in any calendar week except during an extraordinary emergency.

### New York City

**Syphilis Clinic Opened.**—The New York Hospital recently opened a syphilis clinic in the Lenox Hill-Kipps Bay district. It is planned that this shall be a demonstration unit for handling the disease in a densely settled metropolitan area and also a teaching unit for the training of medical students in treatment and epidemiologic methods of study. Patients seeking admission from the district will be charged regular outpatient rates if able to pay, but no patient residing in the district will be refused admission. Patients from other districts will pay regular charges.

**New York University Alumni Meeting.**—The medical program of the annual Alumni Day of New York University will be held February 20 at the new building at Twenty-Eighth Street and First Avenue. The entire program will be devoted to discussions of diabetes with the following speakers: Drs. Elaine P. Ralli, William E. Studdiford Jr., Katharine G. Dodge, John H. Wyckoff, Edward B. Gresser, Emanuel David Friedman, Arthur M. Wright, Samuel Standard, Emery A. Rovenstine, Harold Brandaleone and Irving Graef. At a luncheon the speakers were Drs. Wyckoff, dean of the medical school; Samuel A. Brown, dean emeritus, and Mr. William M. Patterson, chairman of the alumni fund. In the evening a dinner will be held at the Hotel Roosevelt.

### NORTH DAKOTA

**Bills Introduced.**—S. 103 proposes to repeal the laws regulating the possession and distribution of narcotic drugs and to enact what appears to be the uniform narcotic drug act. S. 109 proposes to permit county welfare boards to establish dental clinics and to provide dental services. In rendering such dental services the board is not to be limited to "actual indigents, but may extend the benefits hereof to cases in which, by reason of limited family means, such services could not otherwise be secured for any minor without reducing said family to a relief status or indigence, and where said minor would, except for the use of such facilities, be required to forego necessary dental treatment."

### OHIO

**Bills Introduced.**—H. 71, to amend the workmen's compensation act, proposes to add silicosis to the list of compensable occupational diseases. The bill proposes, however, that a workman shall not be entitled to benefits for the contraction of silicosis unless he has actually been exposed to silica dust in his employment in the state for periods amounting in all to at least five years preceding his disablement. H. 77, to amend the workmen's compensation act, proposes to add silicosis, asbestosis and anthracosis to the list of compensable occupational diseases.

### PENNSYLVANIA

**Obstetric Institute.**—Dr. John Cooke Hirst, Philadelphia, conducted a series of obstetric institute lectures in the autumn under the auspices of the state health department and financed by social security funds. Dr. Hirst lectured at Altoona, Norristown, Danville, Wilkes-Barre and Allentown. In addition he conducted a clinic at Hazelton and, in association with Dr. Roy R. Snowden, Pittsburgh, another at Uniontown.

**Personal.**—Dr. James F. Schell, Philadelphia, is director of the survey on medical care of the indigent described in THE JOURNAL, January 9, and not Dr. Samuel Horton Brown. According to the *Pennsylvania Medical Journal*, Dr. Brown was first chosen to head the survey but was unable to give sufficient time to the work. Dr. Schell was appointed January 11.—Dr. Frederick J. Bishop, Scranton, recently chosen president elect of the Medical Society of the State of Pennsylvania, was honored by a testimonial dinner given by the Lackawanna County Medical Society at Scranton, December 3. Dr. Charles Falkowsky Jr., Scranton, was toastmaster and Dr. Wilmer Krusen, Philadelphia, made the principal address. The society presented to Dr. Bishop a plaque listing the offices he had held in the organization and his record of service in his thirty years of practice.—Among physicians in the state legislature are Drs. George A. Deitrick, Sunbury, and Leo C. Mundy, Wilkes-Barre.

living births; in other words, twice as many persons died as were born. As the number of marriages contracted is likewise steadily on the wane (within five years the number of marriages has declined by more than 4,000) and as bad economic conditions conduce to the childlessness of most marriages, a rapid aging of the population is surely to be reckoned with. Then too the immigration of outsiders into Vienna affects chiefly the age groups above 25 years, and if the newcomers are married in the capital they will likewise remain childless. Only in the rarest instances do families removing from country to city bring with them minor children.

### SWITZERLAND

(From Our Regular Correspondent)

Nov. 20, 1936.

#### The New Swiss Pharmacopeia

The fifth edition of the *Pharmacopeia helvetica*, which recently became official, was completed in 1935 after some eleven years of work. Critics have repeatedly termed the new book singularly modern and progressive and it is worth while to consider certain innovations in the new edition. It differs so extensively from its predecessor that the Federal Council deserves credit for inaugurating an entirely new standard. Contrary to the tendency of American and British pharmacopeias to reduce the number of official items, this book contains 204 more than the fourth edition (304 added and 100 deleted). The standards for testing have been removed from individual articles and entered under "General Regulations."

The preparations are classified according to whether they are (1) chemically definite pharmacologic materials of organic or inorganic nature, (2) chemically indefinite pharmacologic materials of organic or inorganic nature, (3) pharmaceutical preparations of materials belonging to one of the preceding groups but not definite chemical entities, or (4) serums, vaccines, other immunologic substances and organotherapeutic preparations.

The new edition includes proprietary substances and thus sets standards for their control which was not possible prior to this time. Proprietary preparations of official items must conform with the monograph stipulations, including name, trade marks, identity, purity and label. These labels must have red letters on white paper for potent drugs such as barbital, cantharis and cocaine, and white letters on black paper for poisons such as cocaine, morphine and phosphorus. Local regulations applying to these items must also be followed.

The constituents of official preparations must be designated in terms of weight or, in the case of certain solutions, weight percentages. Medicine glasses indicating teaspoonfuls must have the numbers of teaspoons at 5 cc. intervals, dessertspoonfuls, 10 cc., and tablespoonfuls 15 cc. Potent drugs and poisons prescribed by the drop must be dispensed in dropper bottles or with graduated pipets. Descriptions include the empirical and structural formula as well as the molecular weight and percentage content. They appear under Latin names with synonyms in German, French and Italian—the three languages in which editions of the Swiss *Pharmacopeia* are available.

The scope of the book is extensive, the intent being to include everything the physician should prescribe, including even the brands of gauze and cotton. The new preparations include "Opialum, Opial, P. H." which is a mixture of the hydrochlorides of the principal alkaloids of opium, the principal ingredient being the morphine salt, 66 per cent. It is designed to replace a popular proprietary.

This book contains the usual tables, including one of maximal doses, which in many instances are below those given in the previous edition.

In some respects it is superior to and in others inferior to the official British and United States standards. Of greatest

importance is the fact that it should meet the requirements for the Swiss physicians and pharmacists and on this basis it is superior to the previous editions.

### Death of Sir Arnold Theiler

With the passing, at the age of 69, of Prof. Dr. Sir Arnold Theiler, a native Swiss, the world loses a scientific investigator of the first rank. Sir Arnold had come to London to participate in the second International Congress of Microbiology, but shortly before the opening of the convention death overtook him. Theiler was educated at the Universities of Bern and of Zurich; as a young man he went to South Africa. At first he devoted himself to several specific tasks in the Transvaal, but most important of these was the campaign against rinderpest. At length, after the British occupation of the country, Theiler had placed at his disposal a veterinary research institute at Onderstepoort. These "Laboratories for Veterinary Research of the Union of South Africa," as they were called, expanded under Theiler's skilful direction into a great and celebrated center of research. With the help of a numerous staff of collaborators, Theiler here successfully carried on a vast amount of theoretical and practical work. With the constant growth of the institute, the sphere of its activities became ever wider. In 1910 he was appointed professor of the newly created South African Faculty of Veterinary Medicine. On his retirement from office in 1927, he returned to his native Switzerland but continued to maintain close contact with scientific affairs.

Theiler's achievements went far beyond the sphere of veterinary medicine. The clear, purposeful method which he employed in his campaigns against the diseases of cattle in South Africa was based on strictly scientific foundations. Accordingly he has bequeathed to science a wealth of new important and even basic data, the fruit of his investigations, and above all he has enriched the sum of knowledge regarding the protozoal diseases. The mere mention of a few of Theiler's discoveries suggests the fundamental character of his work of experimentation and investigation: the group of intracellular blood protozoa known as "Theileridae" and their many subspecies; the causative organism of East African intermittent fever of cattle; the *Theileria para*; the *Theileria annulata*; the disparate *Theileria*; the cattle trypanosoma (*Trypanosoma theileri*), and *Spirillum theileri*, a species found on cattle and sheep of the Transvaal. Another of Theiler's great achievements, and one that represented a notable advance in the fight on disease, was his accurate evaluation of the tick as the transmitter of African piroplasmiasis and the exhaustive study of its living habits. He was also the author of numerous works on experimental protective inoculation, serotherapy and the problem of immunization.

### CORRECTION

**Infant Mortality in Rumania.**—In the letter from Rumania published in *THE JOURNAL*, July 11, 1936, the statement was credited to Professor Mezincescu that "50 per cent of infants died before reaching the first year of life, and of those remaining alive only 50 per cent reached the fifth year." He is also credited with saying that the rate of infant mortality is not as low as it was fifty years ago. A correspondent from Rumania submits the following infant mortality rate for the last five years:

Year	Absolute Number of Deaths Under One Year of Age	Rate of Infant Deaths Under One Year of Age for 100 Living Births	Deaths 1-5 Years
1935	112,415	19.2	64,032
1934	111,520	18.2	77,109
1933	103,765	17.4	41,941
1932	122,184	18.5	66,414
1931	109,041	18.0	57,154

will enter the third year of life as compared with 92,837 white infants; 82,903 Negroes and 88,621 white persons will reach the age of 21 and 14,419 Negroes and 29,471 white persons will reach 75. The death rate in the first year of life for Negro males is 87.32 and for white males it is 62.32 per thousand. In the second year the rates drop to 16.57 for Negroes and 9.93 for white children. They decrease till they reach 2.11 for Negroes and 1.47 for white children in the eleventh year and thereafter increase. In the forty-fifth year the rates are 21.81 for Negroes and 8.74 for white persons; in the seventy-fifth year, 87.75 for Negroes and 78.61 for white persons. The maximum expectation of life, which is applied to those who have survived the first year, is 51.08 years for Negro males and 62.04 for white males; 52.33 for Negro females and 64.93 for white females.

**Warning Against Impostor.**—It is reported from Detroit that a man posing as a clinical pathologist is visiting physicians there asking them to endorse checks to pay for repairs on his automobile. He called on one physician, who entertained him for a day and night, during which time he discussed clinical pathology without betraying himself. On the second day he looked at automobiles, appearing to be disgusted with his old one. Later he left his host, saying he wished to go to a bank, but returned shortly, saying that the bank demanded identification. When the Detroit physician said he could not identify him, the visitor exhibited a bank book with a balance of \$678. The physician then cashed a check for \$50 on the Huntington National Bank, Columbus, Ohio. After an hour or more the "clinical pathologist" went out for a shave but telephoned that the Packard service agency was to pick him up and he would telephone later. That was the last heard of him. The Packard station reported they had no car for such a person and the Columbus bank reported it had no account for the man, who called himself Brown, and was about 5 feet 9 inches tall; dark brown wavy, wiry hair, a high forehead, dark skin, large brown eyes; thick skin with deep wrinkles; teeth excellent and very white; weighed about 170 pounds. He wore a dark brown suit with a pin stripe, an overcoat of Oxford gray and a light felt hat.

**Medical Bills in Congress.**—*Bills Introduced:* S. 396, introduced by Senator Steiwer, Oregon, proposes, among other things, to grant pensions to contract surgeons who served in the Indian wars from 1817 to 1898. S. 1237, introduced by Senator Gibson, Vermont, proposes to reenact all laws in effect March 19, 1933, granting pensions to veterans of the Spanish-American War, the Boxer Rebellion and the Philippine Insurrection, and their widows and dependents. S. 1240, introduced by Senator McNary, Oregon, proposes among other things to grant pensions to contract surgeons of the Spanish-American War, including the Philippine Insurrection and the Chinese Boxer Rebellion. H. R. 3859, introduced by Representative Allen, Louisiana, proposes to erect a 300 bed addition to the veterans' facility at Alexandria, La., for the care and treatment of medical, surgical and neuropsychiatric disabilities. H. R. 3867, introduced by Representative Voorhis, California, proposes to provide benefits now accorded to other veterans to persons who served in the Army of Occupation before July 2, 1921. H. R. 3873, introduced by Representative Hennings, Missouri, proposes to prohibit the sale, possession and transportation of cannabis and its derivatives and compounds, except when sold, possessed or transported for medicinal and lawful uses by the producer or manufacturer thereof or dealer therein to licensed physicians, surgeons, dentists, pharmacists, druggists and veterinarians, under such rules and regulations as shall be prescribed by the Commissioner of Narcotics. H. R. 3999, introduced by Representative Hook, Michigan, proposes to erect a veterans' hospital in the upper peninsula of Michigan. H. R. 4004, introduced by Representative Schuetz, Illinois, proposes to add the name of John D. Schwieger to those honored by the act recognizing the public service rendered by Major Walter Reed in the discovery of the cause and means of transmission of yellow fever. H. R. 4010, introduced by Representative Gasque, South Carolina, proposes to provide hospitalization and domiciliary care to former members of the Regular Establishment not dishonorably discharged. H. R. 4013, introduced by Representative Gasque, South Carolina, proposes to grant pensions and increases of pensions to certain soldiers, sailors and nurses of the War with Spain, the Philippine Insurrection, or the China Relief Expedition. H. R. 4094, introduced by Representative Arends, Illinois, proposes to create service origin presumptions for spastic paralysis, chronic arthritis, chronic rheumatism and chronic heart disease, when contracted by veterans of the World War. H. R. 4219, introduced by Representative Wilcox, Florida, proposes to construct a marine hospital in or near Miami, Florida.

### LONDON

(From Our Regular Correspondent)

Jan. 9, 1937.

#### The Influenza Epidemic

A widespread but mild epidemic of influenza is prevalent in the British Isles. Its extent can be judged from the fact that 8 per cent of the London police force are affected, while their normal total sick list is 3 per cent. In Leicester 11 per cent of the factory workers and 40 per cent of the schoolchildren are affected and the street car service has had to be curtailed because of the large number of men who are ill. The Irish Free State Department of Public Health has circularized local bodies urging them to organize health and nursing services, and where an epidemic of influenza occurs warning should be given through the press. The British Ministry of Health has issued the following advice as to the prevention of influenza: Rooms should be well ventilated and airy but not drafty. Nourishing food is desirable. It is often well to take cod liver oil. Gargling is useful. The gargle can be made by adding to a tumbler of warm water either a tablespoonful of compound glycerin of thymol or just enough potassium permanganate to give a pink color. If crowded places are avoided there will be less danger of catching influenza.

Last week 325 deaths were ascribed to influenza in 122 large cities of England and Wales (covering a population of more than 20,000,000) compared with ninety-seven for the previous week. The number of deaths in Greater London (population 8,500,000) was 232. The number of notifications of acute primary and influenzal pneumonia in the whole country was 1,542, against 844 in the previous week. The mildness of the epidemic so far is shown by the fact that the totals of deaths from influenza and notifications of pneumonia are far below the totals for several consecutive weeks throughout the epidemics of 1928-1929 and 1932-1933.

#### Delivery of Virus by Parachute

In the *Veterinary Journal* the chief veterinary officer of the Bechuanaland Protectorate illustrates a new use for the airplane in preventive medicine. Foot and mouth disease was discovered in a herd of native cattle. There were some 261,000 cattle in an area of 60,000 square miles. The whole of the cattle could be quarantined, so that it was possible to adopt preventive virus inoculation of the healthy cattle. The chief difficulty was to transport the inoculation material to the various areas in which veterinary officers work with their staffs. It was impossible for automobiles to reach the infected places, and native runners would have taken at least ten or twelve days. The chief veterinary officer devised a system of delivery by parachute in places where airplanes could not land. It was found that 7 square feet of parachute was required for each pound of weight of load. The parachute consisted of a square piece of calico, of which the four corners were firmly tied to four stout strings about 12 feet long, and the tin was tied to the free ends of these. The parachutes were folded with the strings carefully arranged to avoid tangling and were thrown out of the open door of the cabin of the plane from a height of 500 to 800 feet when gliding into the wind. The parachutes were dropped without a single failure. The report states that the use of the airplane shortened the duration of the outbreak by at least two months and that its value for establishing speedy contact with different parts of the territory is inestimable.

#### The British Medical Journal in New Type

For some time committees of the British Medical Association have had under consideration a throughgoing reform of the typography and layout of the *British Medical Journal*.

Academy of Pediatrics; served during the World War; aged 46; died, Dec. 10, 1936, in the Good Samaritan Hospital, Los Angeles.

**Clarence Lucias Miller**, Topeka, Kan.; Ensworth Medical College, St. Joseph, 1905; veteran of the Spanish-American and World wars; state registrar of vital statistics, state board of health; aged 59; died, Dec. 10, 1936, of tuberculosis of the lungs.

**Francis Joseph Jones** Ⓢ Providence, R. I.; Harvard University Medical School, Boston, 1902; on the staffs of St. Joseph's and Providence Lying-in hospitals; aged 59; died, Dec. 17, 1936, in the Butler Hospital, of cerebral thrombosis.

**Joseph Franklin Ruff**, Clearwater, Fla.; Tulane University of Louisiana Medical Department, New Orleans, 1901; aged 63; on the staff of the Morton F. Plant Hospital, where he died, Dec. 7, 1936, of coronary thrombosis and paralysis agitans.

**Henry V. S. Stout**, Livingston, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1893; formerly on the staff of the Homeopathic Hospital, East Orange; aged 81; died, Dec. 4, 1936, of cerebral hemorrhage.

**Lynn Rogers**, Lafayette, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; also a lawyer; served during the World War; aged 59; died, Dec. 2, 1936, of coronary obstruction.

**Bernie F. Jungkind**, Beebe, Ark.; College of Physicians and Surgeons, Little Rock, 1909; aged 54; died, Dec. 15, 1936, in the Veterans Administration Facility, Hines, Ill., of epithelioma of the nasopharynx.

**Bonaventura De Rosa**, Portland, Ore.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1897; aged 68; died, Dec. 17, 1936, in the Good Samaritan Hospital of cardiovascular renal disease.

**Berthier Whitford Mather**, Boise, Idaho; Albany (N. Y.) Medical College, 1899; member of the Associated Anesthetists of the United States and Canada; aged 64; died, Dec. 13, 1936, of myocarditis and uremia.

**William Wilkins Kain**, Cape May, C. H., N. J.; Jefferson Medical College of Philadelphia, 1893; member of the Medical Society of New Jersey; also a druggist; aged 80; died, Dec. 14, 1936, of lobar pneumonia.

**Samuel Sleath**, Ambler, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1904; on the staff of the Abington (Pa.) Memorial Hospital; aged 62; died, Dec. 7, 1936, of cerebral hemorrhage.

**James Francis Cuddy** Ⓢ Athol, Mass.; Baltimore Medical College, 1905; medical examiner in the Worcester North District and member of the school committee of Athol; aged 54; died, Dec. 3, 1936.

**John C. Robinson**, Henryetta, Okla.; St. Louis College of Physicians and Surgeons, 1890; member of the Oklahoma State Medical Association; aged 70; died, Dec. 9, 1936, of carcinoma of the throat.

**Sidney A. Majure**, Hickory, Miss.; Medical College of Alabama, Mobile, 1889; member of the Mississippi State Medical Association; aged 75; died, Dec. 8, 1936, of cardiovascular renal disease.

**Thomas Jefferson Griffith**, Washington, D. C.; University of Louisville (Ky.) Medical Department, 1873; for many years in the Surgeon General's Office of the Army; aged 85; died, Dec. 4, 1936.

**Henry Grover Kurz** Ⓢ Chicago; Chicago College of Medicine and Surgery, 1909; aged 52; died, January 7, in the Dante Hospital, San Francisco, of rupture of a dissecting aortic aneurysm.

**Arthur L. McInnis**, Enid, Okla.; St. Louis College of Physicians and Surgeons, 1909; member of the Oklahoma State Medical Association; aged 53; died, Dec. 2, 1936, of pneumonia.

**Mathias Schmitz** Ⓢ Deenville, N. J.; University of Buffalo School of Medicine, 1884; house physician at St. Francis Health Resort; aged 72; died, Dec. 1, 1936, of cerebral hemorrhage.

**John Edward McCabe** Ⓢ Providence, R. I.; Tufts College Medical School, Boston, 1914; aged 51; on the staff of St. Joseph's Hospital, where he died, Dec. 13, 1936, of heart disease.

**Xerxes A. Jones**, Detroit; University of Medicine, Indianapolis, 1898; member of the Michigan State Medical Society; aged 61; died suddenly, Dec. 4, 1936, of coronary thrombosis.

**Charles H. P. Slaughter** Ⓢ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1895; aged 62; died, Dec. 25, 1936, of arteriosclerosis and myocarditis.

**Almon Nathan Pierce**, Lake Charles, La.; Pulte Medical College, Cincinnati, 1884; aged 77; died, Dec. 2, 1936, near Pine Bluff, Ark., of injuries received in an automobile accident.

**Ben M. Rosebro**, Richmond, Va.; Medical College of Virginia, Richmond, 1908; member of the Medical Society of Virginia; aged 59; died, Dec. 17, 1936, of pneumonia.

**Joseph Franklin Starrett** Ⓢ Bangor, Maine; Medical School of Maine, Portland, 1898; aged 66; died, Dec. 11, 1936, of valvular disease of the heart and acute nephritis.

**Albert Henry Gill**, Cleveland; Western Reserve University Medical Department, Cleveland, 1901; aged 62; died, Dec. 4, 1936, of lobar pneumonia and pulmonary embolus.

**Roland Barker Whitridge**, Philadelphia; Harvard University Medical School, Boston, 1883; aged 77; died, Dec. 11, 1936, in the Flagler Hospital, St. Augustine, Fla.

**Byron David Henry** Ⓢ Endicott, Wash.; Jefferson Medical College of Philadelphia, 1897; served during the World War; aged 60; died, Dec. 1, 1936, of coronary occlusion.

**B. P. Kimbro**, Monticello, Ark.; Gate City Medical College, Dallas, Texas, 1907; aged 72; died, Dec. 28, 1936, in the Mack Wilson Hospital, of carcinoma of the colon.

**Fred Le Roy Mattern**, Fleetwood, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; aged 56; died, Dec. 10, 1936, of cerebral hemorrhage.

**John James Nelson Jr.**, Columbia, Va.; Medical College of Virginia, Richmond, 1913; served during the World War; aged 48; died, Dec. 3, 1936, of angina pectoris.

**John Grass**, Denver; Rush Medical College, Chicago, 1873; Civil War veteran; aged 90; died, Dec. 3, 1936, in the Mount San Rafael Hospital, Trinidad, of senility.

**John W. Schmelter**, Erie, Pa.; Ohio Medical University, Columbus, 1900; formerly county coroner; aged 69; died, Dec. 9, 1936, of cerebral hemorrhage.

**Edward Jay Miller**, Holyoke, Mass.; New York Homeopathic Medical College and Hospital, New York, 1903; aged 48; died, Dec. 7, 1936, of pneumonia.

**Julius Anthony Weigand**, Elmhurst, N. Y.; University of the City of New York Medical Department, 1894; aged 68; died, Dec. 15, 1936, of heart disease.

**Leon Joseph Lacasse**, Manchester, N. H.; Baltimore Medical College, 1904; aged 56; died, Dec. 4, 1936, of disease of the coronary arteries and embolism.

**Frank Lincoln Sanders** Ⓢ Kansas City, Mo.; University Medical College of Kansas City, 1898; aged 70; died, Dec. 17, 1936, of coronary thrombosis.

**Oliver Augustus Sprague** Ⓢ Turner, Maine; Bellevue Hospital Medical College, New York, 1889; aged 72; died, Dec. 15, 1936, of chronic myocarditis.

**A. J. McCullough**, Checotah, Okla. (licensed in Oklahoma by years of practice); aged 67; died, Dec. 1, 1936, of uremia and prostatic hypertrophy.

**Edwin R. Stauffer**, Cedar Rapids, Iowa; University of Wooster Medical Department, Cleveland, 1879; aged 87; died, Dec. 4, 1936, of uremia.

**Foster Fanning Potter**, New York; University of the City of New York Medical Department, 1880; aged 82; died, Dec. 18, 1936, of pneumonia.

**Richard Coale Price** Ⓢ Morgantown, W. Va.; University College of Medicine, Richmond, Va., 1901; aged 60; died, Dec. 2, 1936, of pneumonia.

**Fred George Russell** Ⓢ Milwaukee; Milwaukee Medical College, 1910; aged 64; died, Dec. 6, 1936, of coronary occlusion and diabetes mellitus.

**William M. Phillips**, Wallace, Va.; University of the City of New York Medical Department, 1870; aged 87; died, Dec. 1, 1936, of pneumonia.

**Francis Murray Phillips** Ⓢ Charles Town, W. Va.; Baltimore Medical College, 1904; aged 65; died, Dec. 9, 1936, of lobar pneumonia.

**Charles L. Hopkins**, Huntington, W. Va.; University of Maryland School of Medicine, Baltimore, 1887; aged 73; died, Nov. 20, 1936.

**Francis Joseph McMahon**, Brookline, Mass.; Tufts College Medical School, Boston, 1911; aged 52; died, Dec. 1, 1936, of pneumonia.

**William B. Foster**, Woodbine, Kan. (licensed in Kansas in 1901); aged 80; died, Dec. 9, 1936, of arteriosclerosis.

**Hein Terhorst**, Minot, N. D.; Chicago Medical College, 1880; aged 80; died, Dec. 8, 1936, of senility.

that the physician and his dependents are often less well cared for than those who pay for medical attendance, so that in many cases one prefers to make an arrangement with the family physician or specialist to pay for all visits.

In the earlier years of his medical practice, Massart replaced other physicians during their absence, and he cites an instance in which the wife of a physician successively consulted five or six obstetricians before deciding on one to take charge of her confinement. Such a practice is excusable if a fee is paid for each consultation but is distinctly an abuse of a custom imposed on us by the code of ethics of our profession. Similar abuses occur in other branches of medicine, especially in the case of the specialties. For the same ailment a circuit of four or five specialists is often followed. This perhaps could be condoned if it were not for the fact that only too often the diagnoses and proposed treatments of the various specialists are compared and unjustifiably criticized. Such criticisms may unintentionally reach the ears of paying patients, to the detriment of the reputation of the specialists. It is gratifying to any medical man to have his colleagues call on him to treat themselves and their families and it is quite human to draw the conclusion that, whenever these colleagues have occasion to call some one in consultation in their own practice or to refer a case to a specialist, the one who had been selected to treat the physician and his family should be called on to render service to the pay case. Many specialists, especially surgeons, complain that they treat physicians and their families, but when the medical man has the opportunity to refer a case, he forgets all about his own preference and gratitude, sending it to some one to whom he is not at all indebted.

Massart cites a case in which a physician asked a well known specialist to travel a long distance to see him in consultation and was quite angry when the specialist refused to leave a busy practice for several days without an adequate recompense. The calling of the specialist was unnecessary so far as the diagnosis and treatment were concerned. The physician, who had been well cared for, simply wished to satisfy a whim that the particular specialist should be called.

There can be no question that the economic situation of many a colleague will not permit the additional burden of payment of medical care for himself and his family, but the duty of one member of the profession to give such care without thought of remuneration must not be abused.

## BERLIN

(From Our Regular Correspondent)

Dec. 28, 1936.

### Research in Genetics

In Germany, so-called empirical hereditary prognosis has come to the fore. A prediction with regard to the offspring of a person whose heredity is defective or whose blood relatives present a hereditary taint is termed a "theoretical hereditary prognosis." But if the hereditary history is unknown or if irregularities are discernible therein the most careful calculations are unable to supply a reliable genetic picture of the generation under observation. Here it is that "empirical prognosis" enters in, a system by which conclusions based on the examination of specific instances are made applicable to the whole. "Empirical prognosis" differs radically from theoretical hereditary prognosis in that it dispenses with a knowledge of the genetic history and of the gene manifestation, with the rôle of the environment and also with the insistence on absolute diagnostic exactitude. Professor Luxenburger of the German Institute for Psychiatric Research at Munich has discussed the question in "Erbarzt." He has assembled the results of his investigation in empirical genetic prognosis. These are arranged according to the four great psychic-hereditary groups in tables 1, 3, 4 and 5.

The figures in table 1 indicate that the rate of probable morbidity of schizophrenia for the children of afflicted parents amounts to 16 per cent. The interrelation of a hereditary prognosis of schizoid psychopathy and the status of the parents with regard to this disease is shown in table 2.

The rates for schizophrenia and for schizoid are dependent on the psychic abnormality of the parents and above all on whether or not the latter are schizoid psychopaths. In schizophrenic families, any nonschizophrenic member who presents no psychic anomalies and who above all is not a schizoid psychopath stands an excellent chance of having hereditarily healthy offspring. Such a prognosis, however, is less favorable if both parents are afflicted.

TABLE 1.—*Empirical Hereditary Prognosis in the Schizophrenic Group*

	Schizophrenia, per Cent	Schizoid Psychopaths, per Cent	Total Number of Adults Investi- gated
Children.....	16.4	32.6	1,595
Grandchildren.....	3.0	13.8	1,293
Nephews, nieces.....	1.8	5.1	2,985
Great-grandchildren.....	...	3.9	71
Grand-nephews.....	1.1	...	...
Grand-nieces.....	1.6	1.9	567
Cousins.....	1.8	9.8	665
Average for the population.....	0.85	2.9	...

TABLE 2.—*Interrelation of a Hereditary Prognosis of Schizoid Psychopathy and Status of Parents*

	Probability of Schizo- phrenia in Child, per Cent	Probability of Schizoid Psychopathy in Child
Neither parent schizoid.....	1.3	2.5
One parent schizoid.....	4.1	8.8
Both parents schizoid.....	12.0	20.0

According to more recent studies of children, the prognosis in these diseases has been improved; the rate of probable peril from manic-depressive insanity is no longer 32 per cent but 24 per cent, which is still high, especially if measured by the incidence of the psychosis among the population as a whole.

The differentiated hereditary prognosis for children of manic-depressive parents is represented in table 4.

From these data it may be concluded that if even one parent is diseased an extremely bad hereditary influence will be exercised and that the magnitude of the transmitted taint is not substantially increased if the other parent is a cyclothymic psychopath. These figures indicate that the earlier hypothesis of the decisive rôle of the dominant traits in the inheritance of manic-depressive disorders is perhaps correct and that only a minor significance is as a rule to be attached to the recessive factors.

As the figures in table 5 show, little is yet known of the probability that children of epileptic patients will present the disease. Still the figure of 10 per cent appears more significant than that of 2 per cent, as it seems to have been based on more careful calculation.

Many new facts have been brought to light in the sphere of hereditary feeble-mindedness. The recessive nature of the inheritance has become evident as well as the fact that persons of "dull mentality" are not to be considered as one with the feeble-minded. This point is provided detailed illustration by table 6.

Investigations of the propagation of schizophrenic subjects have been carried on by Dr. Skalweit of the Psychiatric Clinic of Rostock. He found that the rate is substantially less than

crude and thus intrinsically uncertain in action, and their use frequently improperly conducted, the subject became neglected and even damned by this great leader of medicine.

Jibes were cast at drugs, jibes that now come back as boomerangs to their source. Even such fantastic tales as the age old use of pregnancy urine, sneered at, laughed at and cast out of decent medicine as a disgusting anathema, now reappears as a highly valuable source of most potent, and at that time undreamed of, remedies. About the same time, however, as these things were occurring, and practically unnoticed, was born another daughter to this old queen of medicine. In a quiet little German town Schmiedeberg, following the lead of his master, was laying the foundations of pharmacology, which quite as much as any medical subject—though less spectacularly—has in a few short years become not only an entity but actually a leader. From the time of Lister up to this day, surgery has conferred such benefits on the patient and his harassed and sometimes desperate medical adviser that it has appeared not only to the public but even to the profession itself a logical leader and therefore is entitled to wear the kingly crown of its empire. As I had the honor to express to the late Lord Moynihan some years ago, I would remind the profession and especially my colleagues in surgery that this great tree, warmed by the sun of human necessity, really draws its sustenance from the soil of physiology and with the increased knowledge of function will lose most of its present overwhelming luxuriance. Tumor, for example, which today is the source of so much surgical endeavor, will, and God willing soon, be as much a part of surgery as gummas now are.

Pharmacology, however, unlike surgery, was less spectacular in its immediate appeal. The gigantic growth of more immediate human subjects forced this daughter to become, as it is still largely, the poor little Cinderella of medicine.

Yet even in 1906 Cushny, giving detailed evidence before the Royal Commission for three days, proved with chapter and verse—and how he must have wearied the court—that every drug, bar one (pilocarpine), for the previous twenty-five years had entered medicine through the pharmacologic portals. Since that time, thirty years ago, there have been no therapeutic substances of any value which have been introduced into use except by such experimentation. Furthermore, as my former colleague Dr. Sillar of Edinburgh aptly pointed out, pharmacology has rid its humble house of much superfluous dust.

In place, however, of paying homage to this active and brilliant offspring of its old mother, who has already conferred on man in a few short years such bodies as arsphenamine, anesthetics, local anesthetics, hypnotics, diuretics and new antiseptics, to name but a few substances in everyday use and more recently has shown that all processes in the body are probably controlled by drugs—even the nerve impulse itself ends as a pharmacologic action—medicine, as led by such great and human gentlemen as Osler, still throws its muddy tributes at the now dissected body of *materia medica*, and to some the now infamous "ten drugs" are yet a reality.

Can it be wondered at, then, that the younger men on the one hand, brought up in an atmosphere hostile to the old *materia medica* and while without personal bitterness, regarding the old type of prescription more of historical interest than practical value, and, personally observing the poor physical status of the pharmacologic departments, and, in their clinical years hearing of the distrust in which this subject is frequently held, and even still worse of being compelled to order drugs by a number, or proprietary mixtures, frequently of unknown composition, by their clinical superiors—can it be indeed wondered at that these young men escaping from such chaos fall easy victims to the guiles of the commercial houses, especially when in some cases these actually make a really honest effort to help them by the publication and presentation of convenient

books designed especially for their use, or by the manufacture of preparations easy to prescribe and easy for the patient to take? Can one indeed blame the younger men for prescribing Darke & Lillicome's preparation, knowing it to be a decently made compound, when he is virtually unable, by the break in his own proper training, to prescribe a suitable mixture and fears to try in case he makes a fool of himself.

The perpetuation of therapeutic nihilism and of chaos will continue until proper coordination once more takes place between the basic science and the clinic, and reasonably well trained pharmacologists teach the practical applications of their science. It cannot be too often repeated that a prescription for a disease is useless, for while classic treatment of classic disease is a theoretical ideal, classic disease occurs so rarely in practice that it arouses much interested comment when it does. The doctor, then, has the privilege of giving orders for the treatment of William Brown, who has "bad legs," or of Johnny Jones, who has measles, but he has not yet in these days won the regal privilege of writing prescriptions for "cases" of disease. Medicine and pharmacology have not yet advanced that far, and those who speak glibly or largely of the treatment of "cases" and carry this out in their own practice are either ignorant, careless or lazy medical men. In mass medicine, which sometimes because of economic or other factors exists, short cuts or average methods of treatment are better than none at all; but to lose sight of the sick human being in the treatment of his disease is medicine conducted on its lowest scale and is justifiable only in cases of emergency.

Surgery cannot be learned from books and the lesson that should be derived from the offspring of pharmacology—*anesthetics*—seems never to be assimilated, that drugs, as well as knives, require judgment and experience to use.

In pharmacology with its copartner physiology now to thinking men lies the real hope of controlling and treating animal and human disease. Yet still in many schools this subject is a rather disrespected subdivision of some other overworked department. Until very recently, but now happily corrected, one of the greatest schools in this country and in the world had no department of pharmacology. Another school and an unusually wealthy one still does not have. There are individuals posing as professors of therapeutics who could not pass an honors paper in the elementary knowledge of the drugs they use. Sadly enough there are also individuals who could not intelligently give advice in the practical application of the subject he is supposed to teach.

A good pharmacologist is naturally very close to medicine and only a relatively few hardy spirits have remained faithful to their first but poor love, for only next door is the tempting land of medicine, flowing with the milk and honey of opportunity, filled with the romantic calls of maidens in distress and lighted by the sun of human glory. He has even the knowledge that, should his luck strike gold from the rock of knowledge, roving bandits will most efficiently invade his domain and carry off the booty to become highly paid specialists and experts. Perhaps I have colored this picture somewhat vividly, yet the facts remain and are well enough known to pharmacologists. Therefore, when one reads that the pitiable condition of this great subject is actually attracting attention can you wonder that I rejoice? Can you wonder, then, that I hope that a differential diagnosis, respectfully made in the spirit of Osler, of the condition may receive consideration and that the Council on Medical Education and Hospitals will see fit to prescribe that this member of the medical group shall receive its proper supply of nourishment and vitamins and that it must no longer be considered the kitchen slut among her better favored sisters in her mother's house? Heaven knows I am no Prince Charming to lead a Princess, but even the

organization of the criminologic-biologic service planned by the National Ministry of Justice has helped make this possible. This service renders the hereditary antecedents of criminality more readily demonstrable than was formerly the case. These investigations are to be extended to include all asocial persons. The genetic survey is to be rounded off by a genetic classification of the oldest age group among the school children.

At Bonn, the Rhenish Provincial Institute for Psychiatric-Neurologic Genetic Research has been opened. Professor Pohlisch, director of the university psychiatric clinic, is in charge. This institution houses more than 100,000 case histories. In the center of the building are located the main card catalogue and the collection of genealogical tables. The card index comprises statistical documentary data on more than 300,000 inhabitants of the Rhine Province. Each card sets forth the personal data, the number of times admitted to hospitals and similar institutions and the diagnoses made on such occasions. In addition there are cross references to the records of the person's relatives, if such records are also to be found in the card index, besides cross references to the appropriate genealogical table. A good 50 per cent of persons for whom cards have already been filed represent cases of mental and nervous disease; the other 50 per cent of the cards contain records of the relatives of these persons. The catalogue will be extended to include records of all persons who in the course of the past 100 years have been admitted to any kind of an institution for the mentally deficient within the Rhine Province. This will mean a total of about 500,000 cards without including the records of the relatives. This vast assemblage of material will make possible voluminous research studies of the origins of mental disease. The source material on schizophrenic subjects, for example, already is represented by some 50,000 cards.

##### The National Medical Week

During National Medical Week Dr. Charles Waltner read a paper on the action of cereals on bone development. He examined the action of cereals on the bones by replacing maize flour as the source of starch in the Steenbock-Black mixture with other substances rich in carbohydrates. Severe rickets developed if the mixture contained maize flour, wheat flour, wheat starch or rice starch even when it contained beet sugar. The rickets producing action of maize flour was stopped or reduced by the admixture of the extract of oats or of barley flour extracted with 5 per cent acetic acid. Instead of maize flour and other sources of carbohydrate, he used other sources, which gave the following order of severity of the rickets: tapioca ++++, sago ++, barley flour + and oats flour +. The difference observed in the production of rickets by the various carbohydrate sources depends on their phosphorus content.

##### COBRA TOXIN FOR THE TREATMENT OF NEURALGIA

Dr. Endre Kubányi treated in his clinic a large number of facial neuralgias. His experience is that the causes are traceable in a very small percentage of the cases. Kubányi treated seven patients with cobra toxin. A complete cessation of all pain was attained in two of these patients. In two of the patients there was no effect noticeable, while in the other three patients, who were accustomed to large doses of morphine, the result was uncertain.

##### MUSEUM SPECIMENS PREPARED BY A GALVANOPLASTIC METHOD

Dr. Károly Wolff exhibited museum specimens that were prepared by a galvanoplastic method. Infant corpses with this method can be exhibited as a dry preparation. The method

is successful only in case the skin of the cadaver is freed from all vernix caseosa. After adequate preliminary treatment, galvanization is followed by complete success. The metal deposited on the surface of the skin does not render the structure of the skin invisible, but every wrinkle and fold or the finest warts are strikingly brought out, and the whole cadaver becomes like a statue. As such a preparation is clean, odorless and dry and can be kept in the air without any special protecting case, the method is excellent for the preservation of such specimens as amputated limbs, and larger objects in which the pathologic changes are on the surface.

##### Diet Treatment of Putrefactive Dyspepsia

In a lecture before the Vienna Society of Physicians, Professor Porges discussed putrefactive dyspepsia. Successful treatment will be difficult if the pathology of the disorder is not understood. The disease is first manifested as a recurrent obstipation, then later diarrheal discharges containing bloody mucus appear, an achylia gastrica may be established, complaints of colicky pain are not infrequent and a proctosigmoiditis finally sets in accompanied by all the symptoms of a pronounced putrefactive dyspepsia. Patients usually receive a bland cellulose-free regimen consisting of gruels, mashed potatoes, zwieback, cakes and so on. Nevertheless the already marked emaciation of the patient is seen to progress still further, lack of appetite and vomiting add greatly to his discomfort, and there is a persistent typhilitis with high grade secretion of the diseased cecal mucosa. These secretions decompose, and the products of putrefaction irritate the intestinal mucosa, which in turn reacts by hypersecretion. The motility of the entire large intestine becomes highly irritated by these products of decomposition (it is a question of a putrefaction of the intestinal secretions and not of the chyme) and the result is diarrhea. Professor Porges next outlined the type of dietetic regimen that he uses in the treatment of this disorder. Ten years ago he pointed out that the ingestion of nutriment containing cellulose was important in the dietetic treatment. He prescribes at least 200 Gm. of black bread daily, an equal amount of potato and, in addition, a mixed cellulose-free regimen: meat, eggs, cheese, fruit juices, butter, fats and light amylases. Even if this regimen does not immediately agree with the patients it should not be abandoned, for soon the condition improves and they are able to consume amazing quantities of bread and butter. The diarrhea then quickly ceases, body weight increases rapidly and, if the patient adheres to this regimen, a permanent improvement in general health becomes manifest. An explanation of the favorable effect of this diet is to be found in the fact that fermentable carbohydrates are enabled to reach the cecum in abundant quantity. Within the cecum the ferments work a rapid decrease in the bacteria of putrefaction and in this biologic way the septic dyspepsia is arrested. The readily decomposable amylases are not suitable for the foregoing purpose, as they are already nearly completely absorbed within the small intestine, whereas a considerable portion of the black bread and potatoes, if these foods are administered in sufficiently large quantities, avoids the digestive process of the small intestine and attains the cecum, wherein it is permitted to exercise its function of purification.

##### Decline in Austria's Birth Rate

Figures that have just been made public in the *Statistischen Nachrichten* of the Public Health Bureau might well be the basis for apprehension with regard to the country's future. The nationwide decline in the number of births is quite marked, although there still exists a slight excess of births over deaths. But in Vienna in 1935 there were 25,205 deaths and only 12,179

favorable, no infections followed its use, and the nonirritating properties were commented on by the surgeons using the solution.

These results are surprising, since it would seem reasonable to expect some toxic effects when a 1:1,000 mercury bichloride solution is used in open wounds and even on moderately large areas of intact skin. The inherent danger of this low concentration could be lessened with further dilution, but the optimum for effectiveness and relative safety would be difficult to determine. It must be remembered that the use of effective concentrations of mercuric chloride is not new but its toxicity has given rise to preferences for the less irritating mercurial tinctures. It has been stated that alcohol enhances the disinfectant action of aqueous solutions of mercury bichloride but it has also been claimed that alcohol increases the absorption; hence the toxicity of the solution.

It cannot be definitely stated that the solution proposed by the inquirer would be harmless. Probably some individuals would develop skin reactions and, if used over large areas, mercury bichloride poisoning as a result of its application. It is interesting to note in connection with the question of precipitation of color that the authors encountered a precipitate in this solution. They found that it could be avoided by the use of a specially purified chrysoidin X.

Vaichulus and Arnold noted that it was necessary to keep their solution tightly stoppered and recommended the following modification for practical purposes:

Ethyl alcohol (95%) .....	600 cc.
Acetone U. S. P. ....	200 cc.
Mercury bichloride .....	1 Gm.
Hydrochloric acid (concentrated).....	10 cc.
Chrysoidin Y .....	2 Gm.
Distilled water, q. s.....ad	1,000 cc.

A member of the Council on Pharmacy and Chemistry who was consulted wrote that work not yet published indicates that another similar solution (Harrington's solution):

Commercial alcohol (94%).....	640.0 cc.
Hydrochloric acid (strong commercial).....	60.0 cc.
Water .....	300.0 cc.
Mercury bichloride .....	0.8 Gm.)

is not an efficient skin disinfectant and that when used on the skin it forms a coating which acts as a glove, preventing the giving off of bacteria from the skin but retaining live bacteria within and beneath the coating. For this reason, this and similar preparations would seem to be unsuitable for use when the skin is to be incised or punctured by a hypodermic needle. It must also be borne in mind that the mercurial disinfectants are rather slow in action and within a limited period are bacteriostatic rather than germicidal.

#### RELIEF OF STERILITY AFTER SALPINGECTOMY

*To the Editor:*—A woman, aged 25, who had a bilateral salpingectomy five years ago, necessitated because of a gonorrheal infection, has since remarried and is desirous of having children. She has enjoyed perfect health since her operation. The pelvic examination is normal except for the absence of the tubes. The tubes were probably removed close to the uterus, though no roentgenograms of a transuterine injection have been made to determine the extent of the tube remnants. Is there any type of plastic operation that might be done to reestablish the possibilities of pregnancy for this patient? Please omit name. M.D., Georgia.

**ANSWER.**—The first thing to be done is to make certain that the present husband is capable of procreation. This, of course, may easily be determined by an examination of his semen. If the latter is satisfactory, a hystero-gram should be made by the injection of iodized oil into the uterine cavity. This not only will reveal the size and shape of the uterine cavity but also it may indicate the size of tubal stumps if one or both are present. Regardless of whether or not portions of tube exist, an operation may be done to try to overcome the patient's sterility. However, before operating, it is important to point out to both husband and wife that the chances for a pregnancy are not great and that not infrequently when a gestation does take place a miscarriage results. If the patient and her husband agree to an operation after obtaining this information, a laparotomy should be performed. If there are no remains of either tube, one uterine cornu should be removed and half of the ovary on the corresponding side, still attached to its pedicle, should be implanted over the opening thus made in the uterus. The same procedure should be carried out on the opposite side if both ovaries are healthy. The details of this operation are given by W. L. Estes Jr. (*Surg., Gynec. & Obst.* 38:394 [March] 1924). In a series of fifty cases only four women (8 per cent) became pregnant and only two of these had full term babies.

If tubal stumps are present but there is an obstruction at the uterotubal junction, as demonstrated before operation by

the hystero-gram or more certainly at the time of operation by making an opening in the distal end of the tube and blowing air into the tube with a Luer syringe, the entire tubal stumps must be removed with a portion of the uterine cornu. Following this, half of each ovary should be implanted over the uterine cornu. If, however, portions of each tube are present and there is no obstruction at the uterotubal junction, all that is necessary is to perform the operation known as salpingostomy. The simplest form of this operation consists of slitting open the tubal stump all the way to the cornu and with very fine catgut suturing the tubal mucosa to the serous covering of the tube. After this is accomplished, air should be blown through the new opening into the uterine cavity to make sure of a free passage. Then a few strands of catgut should be led through the open tube into the uterine cavity on each side and left at the uterotubal junction to maintain these openings. In all plastic operations on the tube, great gentleness must be exercised and all bleeding must be checked before the abdomen is closed. When salpingostomy is performed there is not only the increased possibility of abortion but also, and more serious, a definite hazard of tubal pregnancy. In the cases in which a salpingostomy has been performed, a Rubin test or a hystero-salpingogram should be made a few weeks after operation to determine whether the new openings in the tubes are permeable to air or iodized oil.

In general it may be said that a review of the literature concerning plastic operations on the tubes and uterus to overcome sterility does not present a favorable picture for these operations. The chief reasons for this are the relatively few live babies secured by these measures, the disproportionately high number of ectopic pregnancies that have resulted, and other complications that may follow such operations.

#### PERSISTENT VAGINAL DISCHARGE

*To the Editor:*—I am writing you concerning a woman who consulted me some five years ago about the following pelvic lesion. At that time, at the age of 31, she had just married and noted some months afterward a severe itching and dryness of the vulva and vagina. This was followed by a profuse yellowish mucopurulent discharge of foul odor. Being from a prominent family, she hesitated to consult a physician until some six months later, when she presented herself at this office. I immediately referred her to our leading gynecologist. Since that time he has had other gynecologists see her. The treatment to date has been the following: 1. Douches of sodium perborate, mercury bichloride, metaphen, silver. 2. Vaginal suppositories of merthiolate and so on. 3. Solutions of dyes, as methylene blue and acriflavine. 4. Dilatation and curettage, with cauterization of the cervix. 5. Autogenous vaccines made from the discharge (diphtheroid, B. coli, atypical forms of staphylococcus and streptococcus). She has been allowed many rest periods from all treatment. At the present time she is no better. The discharge is copious and of very offensive odor. She has worn a pad for the past five years. She has shunned society and has been practically an invalid since that time. Will you please give me some suggestions as to the type of treatment that should now be instituted or refer me to some gynecologist to whom I may take her. Please do not publish my name. M.D., Ohio.

**ANSWER.**—Although no specific mention is made of the gonococcus, *Trichomonas vaginalis* and monilia, it is assumed that none of these organisms have ever been found on microscopic examination of stained slides or hanging drops. If hanging drop examinations have not been made this should, of course, be done without delay. Although the local treatments have had little effect attention is called to Hitchings reports of the successful treatment of a case of chronic vaginitis with phenylmercuric nitrate in *THE JOURNAL* for Jan. 19, 1935 (p. 212). The insufflation of compound silver picrate powder has been advocated by some clinicians for the treatment of *trichomonas vaginalis* vaginitis. The patient should be instructed to avoid fecal contamination of the introitus to prevent reinfection. At the beginning of the trouble the patient complained of itching and dryness of the vulva and vagina. These complaints occur rather frequently at or beyond the menopause and are associated with "senile vaginitis." In these elderly women, repeated injections of estrogenic substance have proved to be most helpful in many cases. This changes the character of the vaginal mucosa and relieves the symptoms. It may be worth while to give this patient 2,000 international units of estrogenic substance (theelin, amniotin) daily for a few weeks. In addition, a small amount of thyroid substance should be taken daily. The urine should be tested for sugar—a common cause of pruritus vulvae. Perhaps also a vacation away from the patient's present surroundings will help. She should, however, make a strenuous effort to avoid thinking of her present plight and she should become interested in some form of activity. The state of mind and the constitution of an individual may be factors in the persistence of a nonspecific vaginal discharge.

## Marriages

KENNON CHRISTIAN WALDEN, Waycross, Ga., to Miss Anne Lilbourne Gravatt, Blackstone, Va., Oct. 22, 1936.

WILLIAM J. WEATHERFORD, Uria, Ala., to Miss Rachel Milner of Ocean Springs, Miss., Nov. 10, 1936.

AQUILLA RICHARD JOHNSTON, St. George, S. C., to Miss Catherine Deitrick of Richmond, Oct. 24, 1936.

CLAIBORNE BARKSDALE WHITE, Halifax, Va., to Miss Jean Prindle Hardy of Churchland, Oct. 31, 1936.

ROWLAND HILL EDWARDS, Welch, W. Va., to Miss Margaret Hess Hay of Hemphill, Oct. 15, 1936.

SAMUEL HARRY JUSTA, Macclesfield, N. C., to Miss Eva Feldman of Ahoskie, Oct. 25, 1936.

## Deaths

Henry C. Fisher ♂ Brigadier General, U. S. Army, retired, Arlington, Va.; Georgetown University School of Medicine, Washington, D. C., 1891; entered the military service in 1891; was awarded a silver citation for gallantry in action during the Spanish-American War; served in France as chief sanitary inspector, A. E. F., for which he received the Distinguished Service Medal; was cited for exceptionally meritorious and conspicuous service in the Surgeon General's Office, Supply Division, A. E. F.; served in the Canal Zone as chief health officer; formerly commandant of the Army Medical School; was appointed assistant surgeon general with rank of brigadier general in 1929; retired in 1931 by operation of law; was also awarded the Legion of Honor by the French government; fellow of the American College of Surgeons; aged 69; died, Dec. 18, 1936, in the Walter Reed General Hospital, Washington, D. C.

John Alphonse Ragone, Buffalo; University of Buffalo School of Medicine, 1904; member of the Medical Society of the State of New York; associate in pediatrics at his alma mater; was medical director of the Children's Aid Society of Buffalo and Erie County; on the staffs of the City Hospital, Columbus Hospital and the Buffalo Hospital of the Sisters of Charity, Buffalo, and the J. N. Adam Memorial Hospital, Perrysburg, N. Y.; for many years in charge of the Children's Aid Clinic in the Children's Hospital; formerly attending physician at the Buffalo Orphan Asylum, the Crippled Children's Guild and the Fitch Creche Day Nursery; aged 57; died, Dec. 25, 1936, of coronary occlusion.

Martin Rehling ♂ New York; University of the City of New York Medical Department, 1894; formerly associate professor of surgery, New York Post-Graduate Medical School, Columbia University; fellow of the American College of Surgeons; at various times on the staffs of the New York Post-Graduate Hospital, Flower Hospital, Lenox Hill Hospital, the Sydenham Hospital and Bronx Hospital; aged 70; died, Dec. 1, 1936, of cerebral hemorrhage.

Reginald McCreery Rawls, New York; Bellevue Hospital Medical College, New York, 1898; member of the American Gynecological Society and the Medical Society of the State of New York; fellow of the American College of Surgeons; aged 63; served in various capacities on the staff of the Woman's Hospital, where he died, Dec. 30, 1936, of aneurysm of the aorta and cardiovascular disease.

Charles Douglas Kayser, Mount Vernon, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; formerly assistant professor of anatomy at the Fordham University School of Medicine, New York; served during the World War; aged 60; on the staff of St. Joseph's Hospital, Yonkers, where he died Dec. 31, 1936, of cerebral thrombosis and arteriosclerosis.

George David McGregor ♂ Charlotte, N. C.; University of Virginia Department of Medicine, Charlottesville, 1925; formerly secretary of the Mecklenburg County Medical Society; on the staffs of the Nalle Clinic, St. Peter's Hospital and the Mercy Hospital; aged 35; was found dead, Dec. 9, 1936, of injuries received in an accidental fall from a window.

William Easley Morris, Mount Kisco, N. Y.; University of Texas School of Medicine, Galveston, 1927; member of the Medical Society of the State of New York; aged 38; on the

staff of the Northern Westchester Hospital, Mount Kisco, and the Grasslands Hospital, Valhalla, where he died, Dec. 9, 1936, of streptococcal meningitis with brain abscess.

Henry G. Sandlin, Richmond, Ky.; University of Louisville Medical Department, 1893; member of the Kentucky State Medical Association; past president of the Madison County Medical Society; for many years chairman of the board of education and county board of health; on the staff of the Pattie A. Clay Infirmary; aged 67; died, Dec. 20, 1936.

James Knox Smith ♂ Texarkana, Ark.; Medical Department of Grant University, Chattanooga, Tenn., 1903; member of the State Medical Association of Texas; fellow of the American College of Surgeons; on the staff of the Michael Meagher Memorial Hospital; aged 58; died, Dec. 28, 1936, of injuries received in an automobile accident.

Frank Sherman Hough, Sibley, Iowa; Michigan College of Medicine and Surgery, Detroit, 1890; member of the Iowa State Medical Society; past president of the Osceola County Medical Society; served during the World War; medical superintendent and owner of the Sibley Hospital; aged 71; died, Dec. 3, 1936, of diabetes mellitus.

Theodor Schaps ♂ Chicago; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1920; served during the World War; on the staffs of the Alexian Brothers' Hospital and the Evangelical Deaconess Hospital; aged 46; died, Dec. 11, 1936, of cirrhosis of the liver, gastric hemorrhage and pneumonia.

Joseph P. Pecival ♂ Berwyn, Ill.; John A. Creighton Medical College, Omaha, 1896; for many years connected with the Cook County Psychopathic Hospital, Chicago; formerly superintendent of the State Hospital, Norfolk, Neb., and the Chicago State Hospital; aged 71; died, Dec. 27, 1936, of bronchopneumonia.

Hugh Arthur Grant ♂ Potsdam, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1892; president of the board of Potsdam State Normal School; aged 66; on the staff of the Potsdam Hospital, where he died, Dec. 16, 1936, of cardiac decompensation and cerebral hemorrhage.

Samuel Louis Friedman, Brooklyn; Long Island College Hospital, Brooklyn, 1914; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; on the staffs of the Cumberland Hospital and the Beth-El Hospital; aged 57; died, Dec. 26, 1936.

Elam Albert Reeves ♂ Kansas City, Kan.; University Medical College of Kansas City, 1903; past president and secretary of the Wyandotte County Medical Society; served during the World War; on the staffs of the Bethany and Providence hospitals; aged 65; died, Dec. 5, 1936.

Melville F. Miller ♂ Wadsworth, Ohio; Western Reserve University Medical Department, Cleveland, 1892; past president of the Medina County Medical Society; on the staff of the Wadsworth Municipal Hospital; aged 71; died, Dec. 19, 1936, of cerebral hemorrhage.

Robert Lovell Samuel, Maysville, Ky.; University of Louisville Medical Department, 1920; member of the Kentucky State Medical Association; city physician and member of the board of education; on the staff of the Hayswood Hospital; aged 48; died, Dec. 11, 1936.

William Aloysius McGowan, Richmond, Va.; Medical College of Virginia, Richmond, 1897; member of the Medical Society of Virginia; served during the World War; aged 61; died, Dec. 7, 1936, in the Veterans Administration Facility, Washington, D. C.

Robert Hurst Snowden ♂ Buchanan, Mich.; Northwestern University Medical School, Chicago, 1906; past president of the Berrien County Medical Society; served during the World War; aged 57; died, Dec. 19, 1936, in the Epworth Hospital, South Bend, Ind.

William B. Eicher, Peoria, Ill.; Keokuk (Iowa) Medical College, 1898; member of the Illinois State Medical Society; aged 67; died suddenly, Dec. 7, 1936, in the Illinois Central Hospital, Chicago, of suppurative diverticulitis and multiple liver abscesses.

Albert Monroe Miller, Holliston, Mass.; Dartmouth Medical School, Hanover, N. H., 1882; at one time member of the board of health of Needham, health officer and school physician; aged 79; died, Dec. 1, 1936, in the Glover Memorial Hospital, Needham.

Donald Kendrick Woods ♂ San Diego, Calif.; Rush Medical College, Chicago, 1913; member of the American

ambulatory and four hospitalized. In three cases a temporary resolution of the dermatoses was obtained, while in the remainder the results were negative. He comments that the constancy of the relapses on the one hand, and the inconstancy of therapeutic success on the other, exclude the possibility of obtaining an absolute cure.

Wrong (*Brit. J. Dermat.* 45:244 [June] 1933) also reported on a series of ten cases. He weighed his scales and added 1 cc. of sterile physiologic solution of sodium chloride to each 10 mg. of scales. Fifty mg. of scales was injected at one time. He comments that patients must have large plaques of scales in areas suitable for scraping, that it is useless to use the treatment on patients who have shown spontaneous improvement, and that the injections are painful to some patients. One of his patients was treated entirely with scales from another patient, and the condition cleared completely. In his series of ten patients, five definitely improved, one slightly improved, and four showed no improvement.

#### HEALTH DANGERS OF STREAM POLLUTION

To the Editor:—I have been trying for several years to clean up an unhealthful condition of a brook that runs through the center of Brattleboro for a distance of 3 miles. This brook carries a very heavy deposit of sewage. Many private sewers do not reach the water but deposit the sewage on the banks, where it is dried out by the sun and blown about everywhere. The water becomes very low in the summer, making conditions even more insanitary. Numerous samples of the water have been sent to the state hygiene department, and the return reports stated that the water was highly polluted. I have been told by one of the local physicians that, if I wrote to you, you might be able to give me information with regard to the various diseases that might be contracted from water showing sewage pollution and also some information about the possibility of contracting diseases from air-borne pollution. A prompt reply would be appreciated, as the matter has gone as far as calling a special town meeting to discuss this serious condition.

JASON E. BUSHNELL, Health Officer, Brattleboro, Vt.

ANSWER.—Perhaps the most important health hazard that might result from the pollution of the brook referred to would be the possibility of typhoid fever and amebic dysentery. This would be particularly true if there is any local condition that might permit water from the brook to pollute a source of drinking water.

In some of the areas of the Middle West there have been reports of the transmission of intestinal parasites from animal to animal as the result of pollution of brooks and streams flowing through pastures, and a certain species of mosquito breeds prolifically in sewage-polluted waters; but as a rule these are not the types which transmit disease. There is always a hazard of infection by persons who may use the brook for swimming or bathing. If the polluted brook passes through a golf course, the possibility of infecting caddies and players who may pick balls out of the brook is always present.

The possibility of contracting disease from the air as the result of a polluted brook is considered remote.

#### TOXICITY OF TETRACHLORETHYLENE

To the Editor:—A patient now working as a cleaner and exposed to heated fumes of perchlorethylene (tetrachlorethylene) has developed nausea, precordial pain, anorexia and inertia. Please advise as to treatment and as to precautions he should take. M.D., North Carolina.

ANSWER.—The extent of toxicity of tetrachlorethylene,  $\text{CCl}_2:\text{CCl}_2$ , may be gaged by comparison with the toxicity of carbon tetrachloride. If the toxicity of the latter is rated as 1, tetrachlorethylene may be rated at 1.6; that is, more than 50 per cent more toxic. However, this statement applies chiefly to vapors of tetrachlorethylene. When taken into the body by mouth, under proper conditions little is absorbed and consequently the toxicity is low. This has led to the extensive use of tetrachlorethylene as an anthelmintic.

The symptoms mentioned in the query are consistent with a diagnosis of tetrachlorethylene poisoning. Assuming such a condition to exist, prevention of further exposure is the best form of treatment for these milder cases. Symptomatic treatment may be required, but, in the absence of additional exposure, complete recovery is expectable with or without treatment, and in a short time, such as one week. In connection with treatment, the drinking of milk is helpful.

This worker should not be long exposed to a concentration of tetrachlorethylene vapors of more than 100 parts per million of air. The measurement of these vapors on a quantitative basis is difficult, calling for special equipment such as thermal conductivity apparatus or a combustible gas indicator. It is believed probable that such equipment may be found in the

newly created Division of Industrial Hygiene in the State Department of Health in North Carolina.

There is no practical respirator that may be worn with comfort over long periods which will protect workers in chlorinated hydrocarbon vapors. One of the chief requirements in the use of tetrachlorethylene in dry cleaning under conditions that give rise to vapors in the workroom is the installation of exhaust systems at floor levels. Vapors of tetrachlorethylene are considerably heavier than chloroform and build up at lower levels in the absence of evacuation. Completely enclosed dry cleaning systems are preferable when synthetic detergents such as tetrachlorethylene are in use.

#### KAHN TEST IN SYPHILIS

To the Editor:—A woman, aged 35, with three children, the youngest of whom is 11 years of age and no miscarriages, and with a negative family history, had so-called bronchitis about eighteen years ago. X-ray examination now shows very extensive healed miliary tuberculosis, with some apparent present infection of the respiratory tract. There is no cough or expectoration and the x-ray diagnosis is "no active pulmonary tuberculosis." The patient has been quite weak without apparent reason, unless the weakness is due to the respiratory infection. The urine is normal. Red blood cells number 4,460,000, white blood cells 7,000; the hemoglobin is 70 per cent. The Kahn reaction is one plus; spinal puncture was refused. There are no clinical symptoms of syphilis. Kindly give me your opinion as to the Kahn reaction in absence of clinical symptoms of syphilis. What is the proper procedure? I am giving injections of iron arsenite and also a bismuth compound and cod liver oil capsules, but no potassium iodide so far. How soon should I repeat the Kahn test? After the administration of a bismuth compound, potassium iodide and nearsphenamine should I consider the Kahn reaction indicative of present syphilis without clinical evidence or history?

M.D., Ill.

ANSWER.—A one plus Kahn reaction (or Wassermann reaction), in the absence of clinical evidence or a history of infection, cannot be taken as establishing a diagnosis of syphilis. There is no indication from the data presented that the symptoms shown by the patient are due to syphilis; the data indeed suggest that they might be due to an infection of the respiratory tract. Although the Kahn reaction is recognized to be highly specific for syphilis, a borderline reaction, such as a one plus or plus minus, in the absence of clinical evidence or a history of syphilis cannot be considered as justifying antisyphilitic therapy. A borderline reaction should be looked on as an indicator for further clinical and serologic studies.

#### TREATMENT OF STRONGYLOIDES INFESTATION

To the Editor:—A man, aged 35, complains of some indigestion and occasional diarrhea. General physical examination is negative except for a mild secondary anemia; the urine is normal. Examination of the stool shows strongyloides. Apparently gentian violet is one of the latest methods of treatment. By mouth the dose advised seems to vary from 30 to 300 mg. If this treatment fails, I notice that one authority advises the simultaneous use of antimony and potassium tartrate intravenously, a total dose of 2.5 Gm., with intermission of a few days between treatments. Another authority advises gentian violet 20 cc., 0.5 per cent intravenously, or even double this dose. There is also the transduodenal instillation of glycerin, magnesium sulfate and hot saline solution. Are there any possible untoward effects from gentian violet (1) by mouth, (2) intravenously, (3) and from antimony and potassium tartrate, and should this be repeated? What is your opinion as to the best method of treatment?

SAMUEL L. INMERNAN, M.D., Philadelphia.

ANSWER.—1. Excessive dosage may produce local irritation, chiefly vomiting and diarrhea.

2. Intravenous injection of the dye in doses of 5 mg. per kilogram of body weight causes marked blueness of the skin, probably chiefly from the intense color of the dye. The color disappears in a few hours. It is also liable to cause "colloid-oclastic reactions," such as chills and fever, on intravenous injection, and it is probable that its therapeutic effects when given intravenously are due to this reaction. The concentration of the solution should not exceed 0.5 per cent, as a 1 or 2 per cent solution has a tendency to cause thrombosis.

3. The intravenous use of antimony and potassium tartrate (1 per cent in physiologic solution of sodium chloride, initial dose 0.04 to 0.06 Gm.) is liable to be followed by an irritative cough, a metallic taste, nausea and vomiting, colic, diarrhea, and occasional skin rashes. As it is rather rapidly eliminated, there is relatively little danger of cumulative action, so that repetition at adequate intervals may be safe.

The therapy recommended consists of administration of oil of chenopodium, after a day of magnesium sulfate purgation and light meals. It is given in 0.5 cc. capsules at 7, 8 and 9 o'clock in the morning: a total of 1.5 cc. Two hours later a

## Correspondence

### RECENT GRADUATES AND DRUG NIHILISM

To the Editor:—The article by Dr. Norman A. David in THE JOURNAL Feb. 1, 1936, page 405, entitled "The Recent Graduate and Drug Nihilism" is one that should appeal to every teaching pharmacologist. It draws attention to the impoverished condition of this subject. The more recent article "The Present Status of Research and Teaching in Pharmacology," by Dr. David and George A. Emerson (THE JOURNAL, Nov. 14, 1936, p. 1599) stimulates me to forward the accompanying discussion, which I am especially free to do from my present position, as pharmacology has been for many years granted equal rights with her usually more fortunate sisters.

A number of years ago, while professor of pharmacology in Halifax, Nova Scotia, I became unfavorably impressed with the amount of poor prescribing, lacking both in fundamental knowledge of the subject and even more frequently in its practical application. Through the courtesy of my friend Dean Bubridge of the Pharmacy School and chairman of the Canadian Pharmaceutical Association, a somewhat similar inquiry concerning the average prescription as reported in Dr. David's article was conducted. About 200 replies were obtained from druggists in Canada who had analyzed the last one or two hundred medical prescriptions on their books. These showed that over 25 per cent were entirely composed of, or contained, proprietary medicines. Town doctors rated higher than country. The age of the prescriber was not obtained but would have been very interesting.

Shortly after, I wrote an article (*Canad. M. A. J.* 18:565 [May] 1928) in which at least one factor certainly involved in this unhappy condition was discussed, namely, the retained teaching of the degenerated remnants of the old "prescription" which had, or were supposed to have, intrinsic virtues, in place of training young medical men to write an intelligent order in its simplest terms compatible with clarity to his pharmaceutical colleague, attention however being paid to the fact that such an order, however simple, is essentially a responsible one and at any time may have legal significance.

Certain states, however, still ask examination questions which are at least in part based on this out of date type of materia medica, and duty to the student demands that a teacher in such states take cognizance of this fact and prepare his students accordingly. Thus he becomes unwillingly a party in the preservation of some old medical dead wood. However, as pharmacology in the medical school essentially consists of taking medical students around part of the medical tool shops and explaining how to use the tools, it must therefore derive a great part of this energy from the spirit of practice, much as medicine itself does. Thus, it is consistent for the teacher to make the best out of a bad job, as he needs must in practice, and show his students the way over his official hurdles. I am aware that this statement may occasion much adverse comment from some of my colleagues who, quite rightly, insist on the scientific basis of this subject being of paramount importance, especially in a university training; furthermore, that nothing which may assist weaker men in a medical school in their constant efforts to reduce the training to a mere technical status should be encouraged, even by compromise. However, two facts exist: the first, that no medical curriculum is sufficiently long to train fully a student in the science of pharmacology; and the second that human pharmacology can be learned only in the appropriate animal houses, namely, the hospital, clinic, or general practice, with but few exceptions.

There is thus a scientific as well as a practical need for close cooperation between the two types of experimental pharmacologists; namely, those who work largely on animals and those who use chiefly human material. To focus then a medical student's attention largely toward human pharmacology encourages him in his studies of this science, as well as rendering his brief stay in the department of greater value to him. Furthermore, I find by experience that as the student realizes for himself the practical difficulties which always exist in the conduction of human experiments he is more willing to consider and avail himself of the advantages of animal experimentation. On the other hand, just as the various branches of applied medicine have their specialists, owing largely to the overwhelming literature in each subject, so must human pharmacology be considered a specialized branch, and for the same reason. In the clinic no one feels ashamed to consult a specialist in eyes, and ear departments exist all the time as separate entities and their staffs teach the students without raising adverse comment. Yet most medical men equally unspecialized strongly resent even a mild implication that their knowledge of human or general pharmacology is not complete. The consequence is that many chairs of pharmacology have been filled with general practitioners who are no more capable of fulfilling the duties of the position than they would as head of the department of surgery. It must also be added that the same criticism can be fairly leveled against men trained in pure science, such as chemistry, holding such positions.

While, then, one small fault lies in the type of examinations set by certain state boards, and with due respect to Dr. David, I might suggest that these are largely in the hands of the older generation who, while unquestionably better trained in materia medica and the application of the now unnecessary Latin [sic] adornments, are less familiar with the pharmacologic behavior of drugs than some of their younger colleagues. A second and more serious difficulty lies in the fact that unsuitably trained persons have been engaged in the teaching of this science. This difficulty, serious enough in all consequence, is nevertheless merely the outcome of one which is of fundamental importance.

Materia medica in the old days was an important branch of medical learning and was, of course, intimately associated with the practice of medicine. Automatically, then, the teacher was accorded respect with his professional colleagues. Materia medica also for the greater part of medical history supplied the methods of treatment and, indeed, still earlier in the dim ages was medicine itself. With the sudden and startling development of medical inquiry beginning with Harvey, the almost fantastic success of surgery—still, however, dependent on pharmacology for its essential possibility, namely, anesthesia, analgesia, disinfectants—and the magnificent advances in pathology, bacteriology and physiology, the high estate of materia medica became overshadowed, ill nourished and even dismembered.

The inevitable process of debunking, which new knowledge ever causes, not only cast mud on the now half-starved, impoverished medical member but even on occasion denied it its proper right to exist.

At the peak of the flood of medical advancement of the last generation was found that great leader of medicine and of men, Sir William Osler, who, imbued with such desire to understand medicine and unable, being human, to be colonel of each and every one of its many companies, not only neglected to help this old, great field of endeavor, but also, though probably unwittingly, became its most deadly enemy, especially in this country. Blinded by the glory and light that differential diagnosis was bringing to medicine, men tended to forget that the patient still needed comfort and help exactly as he did before. Because knowledge failed and because drugs were still

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, February 6, page 498.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants will be held in various cities throughout the country on April 17. Oral examinations for Group A and B applicants will be held in Philadelphia, June 7-8.* Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination will be held simultaneously in different centers of the United States and Canada in March. Practical examination will be given in St. Louis in April and at Philadelphia in June.* Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B applicants will be held in various cities throughout the United States and Canada, March 6. Practical, oral and clinical examinations for Group A and B applicants will be held at Atlantic City, N. J., June 7-8. Applications must be received at least sixty days prior to the examination dates.* Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Philadelphia, June 12. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Chicago, March 26-27. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Michigan.

AMERICAN BOARD OF PEDIATRICS: Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF PSYCHIATRY & NEUROLOGY: Philadelphia, June. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., June 4-6. Sec., Dr. Byrl R. Kirklind, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Oral examination.* Minneapolis, June 25-26. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

### New Jersey June and October Examinations

Dr. James J. McGuire, secretary, State Board of Medical Examiners of New Jersey, reports the written examinations held in Trenton, June 16-17 and Oct. 20-21, 1936. Both examinations covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and seventy-four candidates were examined, 168 of whom passed and 6 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....	(1935)	86.1, 87	
University of California Medical School.....	(1936)	84	
Yale University School of Medicine.....	(1934)	84.6, (1935) 85.5,

humblest mongrel can snarl and bite in the service of his mistress, and love takes no account of palaces.

To Dr. David, then, I and all pharmacologists owe a debt of gratitude for ably bringing into the light of day his data, and it is to be hoped that his work, aided by the Council, will grow and develop to a proper fruition.

O. S. GIBBS, M.B., Memphis, Tenn.

Chief of Pharmacological Division, University  
of Tennessee College of Medicine.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### BLOOD SEDIMENTATION TESTS

*To the Editor:*—What is the present status of the blood sedimentation test as compared with the leukocyte count (total and differential, including "stab" count) in the diagnosis of chronic and acute infections? In what circumstances is it especially valuable? What is the technic? Please omit name.

M.D., California.

**ANSWER.**—The blood sedimentation is more rapid in disease than in health, but this test is not diagnostic of any one disease. The sedimentation test is useful in differential diagnosis. It is of value in following individual cases. In tuberculosis the increased rate parallels the increase in activity. A normal or slowed sedimentation rate speaks against infection.

The sedimentation velocity is accelerated in active tuberculosis, acute inflammations, infectious diseases, carcinoma, pregnancy and rheumatoid arthritis, and following operations as a result of tissue trauma. In general the rate remains increased after the leukocyte count and temperature have returned to normal.

The chief value of the sedimentation test is in distinguishing between inflammatory and noninflammatory processes and in estimating the activity or progress of pulmonary tuberculosis. In acute inflammations the rate is increased. An actively growing cancer is likely to give a greater rate than a slowly growing scirrhous carcinoma. There is usually an increase in serum globulin and fibrinogen in conditions with rapid sedimentation.

Leukocytic changes are more valuable indicators in the early stages of disease than they are in marking the completion of recovery. The cell sedimentation rate usually tells more regarding end stages of disease. The sedimentation test shows more constant deviation from normal than does the Schilling count in acute and subacute pelvic infections.

The reaction of the leukocytes is somewhat specific for certain types of infection, but the tissue involved plays a part. Infections due to cocci give rise to a leukocytosis by causing an increase of polymorphonuclears. A differential count, special note being taken of the ratio of young or stab forms to mature cells, yields more information than the total count. With severe infections the percentage of young or unsegmented polymorphonuclears increases. Normally there are from 5 to 20 per cent. The pneumococcus produces the greatest leukocytosis. The degree of leukocytosis also depends on the reaction of the individual to a severe infection. If a very toxic infection develops, the leukoblastic bone marrow areas may fail to produce leukocytes even in normal numbers.

Bacillary infections, especially typhoid, paratyphoid, influenza and tuberculosis, rarely produce an increase in the total white blood cell count.

The tissue involved influences the leukocytic picture even more than does the type of organism causing an infection. Diseases involving chiefly the lymphatic tissue (tuberculosis, typhoid and so on) usually have a low total count and a high percentage of lymphocytes. When these infections spread to the bones or serous surfaces there may be a polymorphonuclear cell increase. In diseases with a leukocytosis the blood count usually returns to normal before actual recovery has occurred. A continued leukocytosis suggests rapid extension of the infection.

Hemorrhage into a serous cavity causes a prompt and marked leukocytosis. It begins within two hours and reaches its maximum in from six to ten hours. Many patients with malignant tumors have a leukocytosis resulting from secondary infection or absorption of necrotic tumor tissue. A steadily increasing count suggests rapid growth or metastases.

There are so many modifications of the sedimentation test that it is difficult to compare results. Three methods are chiefly used: the Cutler method, the Westergren method and the Linzenmeier method. Corresponding values for the three methods are discussed by Esther M. Greisheimer, A. E. Treloar and Mary Ryan (*Am. J. M. Sc.* 197:213 [Feb.] 1934).

The simplest of the three methods is the Linzenmeier, which is performed thus: Into a sterile 1 cc. syringe draw 0.2 cc. of sterile 5 per cent sodium citrate and then blood from the vein up to 1 cc. Place in a special tube (5 mm. internal diameter with a 1 cc. graduation mark at 50 mm. height, and two other marks at 12 and 18 mm. below the 1 cc. mark). Mix and set in a vertical position. Record the time when the cell column reaches the 18 mm. line. This is normally about two hours or longer. The normal sedimentation in one hour is from 2 to 10 mm. in men and from 2 to 15 mm. in women.

All three methods are described in the Synopsis of Clinical Laboratory Methods by W. E. Bray, St. Louis, C. V. Mosby Company, 1936. This small book is one of the best and most up-to-date laboratory manuals.

### MYASTHENIA GRAVIS

*To the Editor:*—At present I am giving a 17 year old white girl a half grain (0.03 Gm.) of ephedrine in divided doses and one package of gelatin daily in the treatment of a case of myasthenia gravis. The patient has been under this treatment only a week but seems to have gained strength already. The paralysis of the muscles of deglutition is not so marked and she has better control of the eyelids. When first seen the girl could not talk but had to communicate with me through writing. Is glycerin, strychnine, epinephrine, solution of posterior pituitary or high voltage roentgen therapy over the thymus advisable? What form of treatment has proved most satisfactory? Were heavy doses of quinine sulfate contraindicated for tertian malaria in this case? The patient received 30 grains (2 Gm.) daily for five days. They were only the usual quinine therapy sequelae. Please omit name.

M.D., Arkansas.

**ANSWER.**—If there is enlargement of the thymus gland, demonstrable by roentgen examination, high voltage roentgen therapy might be worth trying. In other cases the administration of thymus gland has been advised. The other remedies mentioned are merely of possible symptomatic value. So is more recently advocated prostigmine (a derivative of physostigmine), which in doses of 0.05 mg. may whip a patient through a crisis. The therapy employed is essentially correct except that a more adequate supply of aminoacetic acid is indicated. The dosage of Aminoacetic Acid, N. N. R., is 20 to 30 Gm. daily. Gelatin contains only 25 per cent of aminoacetic acid. There is no reason to believe that the quinine therapy aggravated the condition.

### SOLUTION FOR USE AS SKIN DISINFECTANT

*To the Editor:*—Would it be advisable to use a solution of mercury bichloride 1:3,000 in 50 per cent alcohol and 10 per cent acetone as an inexpensive bactericidal substance to be painted on very small areas of skin previous to inserting a hypodermic needle for injections? Such a solution represents an important saving over the expense of the ordinary antiseptic solutions. Is there anything harmful about it? Is it bactericidal for ordinary skin organisms? Do you know of any substance that may be added to it to color it, which will not be precipitated by the mercury bichloride?

NORMAN J. KILBOURNE, M.D., Los Angeles.

**ANSWER.**—Clinical experience with the following solution, similar to the one described in the query, was recently reported by J. A. Vaichulus and Lloyd Arnold (Compound Colored Alcoholic Solution of Mercuric Chloride for Skin Disinfection, *Surg., Gynec. & Obst.* 61:333 [Sept.] 1935):

Ethyl alcohol (95%).....	525.0 cc.	50.0 %
Acetone U. S. P.....	100.0 cc.	10.0 %
Mercury bichloride .....	1.0 Gm.	0.1 %
Hydrochloric acid .....	7.5 cc.	0.75 %
Chrysoidin Y .....	2.0 Gm.	0.2 %
Distilled water .....	367.5 cc.	.....

The authors were able to prepare the solution for \$1.60 a gallon. They stated the price of tincture of iodine U. S. P. to be \$4.02 a gallon, 3 per cent of tincture of iodine \$2.65 a gallon and tinctures of metaphen, of merthiolate and of mercurochrome very much higher. They found it more efficacious than other solutions commonly used for antiseptics and skin sterilization (phenol coefficients: compound alcoholic solution of mercury bichloride colored 357, tincture of iodine 128, tincture of metaphen 57, tincture of merthiolate 83, tincture of mercurochrome 1.8). They note its use in 300 cases of gunshot wounds, automobile accidents and "other similar emergency hospital cases" as well as in cases of neck surgery and 120 cases of abdominal surgery. The authors state that the reports were

book with the assistance of his secretary, his associates, his students and also from his private letters and diaries. The subject of the volume led a most interesting life in medical organizational affairs, in literature and in many other capacities. All those who were associated with him in his career (and they were legion) will find the volume fascinating. Every medical student should find in it a source of inspiration.

**Textbook of Surgical Nursing.** By Manelva Wyke Keller, B.S., R.N. Third edition. Cloth. Price, \$3. Pp. 504, with 127 illustrations. New York: Macmillan Company, 1936.

While most textbooks on surgical nursing are essentially abbreviated works on general surgery, it is not so in this case. This excellent and practical book was written for nurses by a nurse with wide experience in surgical and operating room nursing and teaching and is now in its third edition. The text provides only such information about surgical conditions and operations as nurses ought to have to give the patient intelligent care. In the twenty chapters little is said of etiology and nothing of diagnosis, but a great deal of the things which surgical nurses have to know and have to do. The material is presented in clear, simple style. It is illustrated well and abundantly with excellent photographs and line drawings.

**Experimentelle og kliniske Undersøgelser over Rodbehandling af Tænder med Højfrekvent Vekselstrøm (Diathermi).** Af Ove Brinch. Paper. Pp. 210, with 46 illustrations. Copenhagen: V. Richters Forlag, 1935.

The author has carried out an extensive clinical and experimental study of the influence of diathermy on the periodontal tissues. The technic consists of the insertion of one needle-shaped electrode into the root canal that is to be treated, while the other electrode is held in the patient's hand. The experimental part was carried out in the teeth of dogs and is illustrated by good and instructive photomicrographs of sections through the treated teeth and their supporting tissues. Bacteria were brought into these dogs' teeth and into extracted human teeth and the influence of diathermy on them was noted. Diathermy was applied also to a large number of clinical patients. On the strength of these results the treatment of root canals with diathermy is considered a useful method which offers the advantage that it reaches areas in the root which are inaccessible by other methods. A comprehensive bibliography of the recent German literature on pulp pathology and treatment is included in this thesis.

**Undersøgelser over Bacteriers Haptenaktiverende Evne samt over F-Haptens Forekomst i forskellige Bacteriearter.** Af Sigurd With. Paper. Pp. 115, with 3 illustrations. Copenhagen: Nyt Nordisk Forlag: Arnold Busck, 1935.

This dissertation is concerned mainly with the occurrence of the Forssman heterophilic antigen in certain bacteria. The first chapter deals with the lipid fraction or hapten of the Forssman antigen and with the power of bacterial suspensions to convert this hapten into a complete antigen. In the second chapter are described the results of efforts to demonstrate Forssman's antigen in certain bacteria by immunization of rabbits and testing the serum for Forssman antibody. The third and last chapter gives the results of a series of observations on the presence of Forssman antibody in the serum of 219 patients suffering from infectious diseases. The book will interest those who are concerned with heterophilic antigens and antibodies.

**Preparation of Scientific and Technical Papers.** By Sam F. Trelease, Professor of Botany in Columbia University, and Emma Sarepta Yule, Head, Department of English in the College of Agriculture of the University of the Philippines. Third edition. Cloth. Price, \$1.50. Pp. 125. Baltimore: Williams & Wilkins Company, 1936.

The usefulness of this manual is indicated by the fact that it now appears in the third edition. It is a straight account of the details of good writing and the preparation of scientific manuscripts with actual examples so as to make the matter quite clear to the author. While the book is calculated primarily for the engineer, it has useful information and advice for those in every field of science. It should not be considered, however, as primarily a book for the physician, since the volume published by the American Medical Association and that originally published by Mrs. Mellish for the Mayo Clinic are preferable for medical writers.

**Undersøgelser af universelle Kulbueleysbades Indvirkning paa experimentel Marsvinetuberkulose.** Af Tage Helms. Paper. Pp. 150, with 5 illustrations. Copenhagen: P. Haase & Søn's Forlag, 1935.

This doctor's dissertation in Danish presents the details of the author's experiments with light treatment of tuberculosis in guinea-pigs. The main outcome of the work may be summarized as follows: Universal irradiation (arc light) of hairless guinea-pigs increased the resistance to tuberculosis in animals that had been infected with small doses of tubercle bacilli or had been treated previously with the Calmette vaccine. This increase in resistance is ascribed to a special action as shown by the hastening of the specific allergic reactions; light treatment of healthy guinea-pigs that were infected later did not influence the course of the tuberculosis.

**Applied Dietetics: The Planning and Teaching of Normal and Therapeutic Diets.** By Frances Stern, Chief of Food Clinic, The Boston Dispensary. Cloth. Price, \$3.50. Pp. 263, with illustrations. Baltimore: Williams & Wilkins Company, 1936.

The author, who is dean of the food clinic in the Boston Dispensary and who has for almost twenty years been a practical dietitian, presents here the material of her daily work. After consideration of the daily food requirements of the body and the consideration of a normal diet, the author considers therapeutic diets in various diseases and the methods of educating patients in the use of suitable diets. Most of the book consists of a series of excellent tables for developing proper diets for all occasions. The volume is one of the most practical and usable thus far available in this field.

**Brookings: A Biography.** By Hermann Hagedorn. Cloth. Price, \$3.50. Pp. 334, with 16 illustrations. New York: Macmillan Company, 1936.

Robert Brookings, founder of the Brookings Institute, was a merchant who was also an educator and a statesman. This volume records the development of his career. Of special interest to the medical profession is the chapter relating to the founding of the medical school of Washington University, in which is given in intimate detail the development of that institution, including the influence of Pritchett of the Carnegie Foundation and of Brookings. The volume is written in a smooth, interesting style. It is nicely illustrated and a fine story of the success of a typical American.

**Probleme der theoretischen und angewandten Genetik und deren Grenzgebiete.** Herausgegeben von H. Böhm, et al. Redigiert von W. F. Reinf. Strahlungen: Wesen, Erzeugung und Mechanismus der biologischen Wirkung. Von Dr. Karl G. Zimmer, Assistant an der Strahlungsabteilung des Cecilienhauses, Berlin-Charlottenburg. Boards. Price, 3.20 marks. Pp. 72, with 40 illustrations. Leipzig: Georg Thieme, 1937.

This little handbook is one of a group of publications on problems relating to theoretical and applied genetics and related subjects. It contains a technical discussion relating to the various forms of radiation, including infra-red, ultraviolet, ordinary light, roentgen and gamma rays, corpuscular rays and cosmic rays, and the physical and biologic problems associated with them.

**A Descriptive Atlas of Radiographs: An Aid to Modern Clinical Methods.** By A. P. Bertwistle, M.D., Ch.B., F.R.C.S. Third edition. Cloth. Price, \$13.50. Pp. 560, with 808 illustrations. St. Louis: C. V. Mosby Company, 1936.

This volume, a revised and enlarged edition, has been compiled from the material of many men. Its purpose is to show what radiology can do, to encourage medical men to resort to this means as an aid in diagnosis, and to help the inexperienced in reading roentgenograms. Only normal and abnormal subjects commonly seen in general practice are included. Accompanying each roentgenogram is an explanatory diagram or paragraph or both. Short medicolegal and anthropologic sections have been started in this volume. Physicians who have had little or no experience with roentgenograms will find this atlas useful.

#### CORRECTION

**Mathews, A. P.: Principles of Biochemistry.**—In the review of this book in THE JOURNAL, January 16, page 230, the reviewer inadvertently confused the volume with the Mathews "Textbook of Physiologic Chemistry." Instead, the volume there reviewed was a short concise textbook, and a new revision of the larger textbook of physiologic chemistry by Mathews will shortly be available.

## TEMPOROMANDIBULAR ARTHRITIS

*To the Editor:*—A man, aged 28, complains of pain in the region of the right temporomandibular joint when he attempts to close his jaw. Something in the joint itself, he says, obstructs the closure. By placing his head so as to stretch the right sternocleidomastoid muscle and then by slow and slight lateral motion of the jaw, he feels (and hears) the "obstruction" slip smoothly out of the way, allowing the jaw to close. Attempts to close the jaw abruptly are unsuccessful and painful. I can feel nothing abnormal on placing my fingers against the jaw when this "slipping" occurs. The trouble is found only in closing the jaw the last few millimeters; no trouble is found in opening it. With the jaw completely closed, no pain is felt as the teeth are clenched or unclenched. Increased pain and difficulty in closing the jaw and a sensation of swelling in the "obstruction" result from the irritation produced by attempts to occlude the teeth. The patient is unable to masticate with his molars, all chewing being accomplished with the incisors. This condition has remained essentially unaltered for two months. Roentgenograms with the jaw in the closed position, taken by a competent roentgenologist, were negative. No ear symptoms, headache, facial pain or change in salivation is noted, and the region of the joint is not tender to palpation either externally or internally. There has been no change in the denture since the removal of the two upper wisdom teeth five years ago. This trouble was first noticed at breakfast the morning after the patient had inadvertently flipped his jaw sidewise while he was throwing stones. Physical examination shows the patient in otherwise perfect health. I would appreciate any suggestions as to procedure in diagnosis or treatment. Please omit name.

M.D., New York.

*ANSWER:*—In the absence of any direct examination and with the limited information furnished, one would be strongly inclined to make a diagnosis of traumatic temporomandibular arthritis. This condition is by no means uncommon and is frequently overlooked. The tenderness is brought about by a sudden stretching of the capsule with a coincident traumatizing of the meniscus muscle. The treatment is simple and consists in giving the joint rest without immobilization. The patient should be carefully instructed to avoid any unusual movement of the jaws during the waking hours, and to avoid yawning and particularly opening the mouth wide in eating or laughing. In other words, the jaw should be kept within moderate excursions at all times. At night the patient should be instructed to wear a bandage from the chin to the head, which will prevent any undue movement during the hours of sleep. This simple treatment should be carried out for a period of several months, eight or ten as a minimum. This will give the capsule time to contract to its normal limits, and when this is accomplished there should be no further trouble. The discomfort will disappear in a week or two after the treatment is begun. The patient should be warned to continue with the management for a protracted period, because with each repetition of the injury the condition becomes increasingly difficult to cure.

## DIAGNOSIS OF HEARING IMPAIRMENT

*To the Editor:*—A woman, aged 36, has been a telephone operator for eighteen years. Her hearing has been impaired for the past six months and she thinks it is due to her occupation. She can hear the spoken voice at 10 feet in the right ear and at 16 feet in the left ear. The Rinne test is negative in both ears; the Weber, not localized. The tympanic membranes are opaque and lusterless and have poor markings. I am wondering if her occupation has caused or influenced the deafness. Ballenger states that telephone operators develop an occupational deafness. Please omit name if printed.

M.D., Arkansas.

*ANSWER:*—So far as the tests in this case are concerned, one cannot judge definitely whether the hearing impairment is due to a lesion in the conduction apparatus or in the perception mechanism. The fact that the tympanic membrane is pale and lusterless would indicate that some involvement of the middle ear or eustachian tube had been present but, of course, that would not preclude simultaneous involvement of the inner ear if such is present. The fact that the Weber test is not lateralized may mean that the two ears are involved to about the same extent. Ordinarily the Weber test is not lateralized with normal ears. With conduction apparatus impairment, the sound is usually lateralized in the worse hearing ear, or, if both have a conduction impairment, in the worse of the two ears. With inner ear involvement the Weber test is usually lateralized to the better hearing ear, or, if both are affected, the fork is heard in the better hearing ear.

Stating that the Rinne test is negative in both ears is not sufficient information for an actual diagnosis. In other words, if the bone conduction is longer than the air and, therefore, the Rinne test is negative but the bone conduction is longer than normal, and the air conduction is considerably shortened as compared with normal, the negative Rinne test means a definite involvement of the conduction apparatus. When the bone conduction is longer than air but both are greatly short-

ened as compared with the normal, there is usually a combination of the conduction and the perception apparatus.

If in the case cited there is impairment of the conduction apparatus, it does not seem likely that the telephone receiver would cause such a condition. If, on the other hand, there is a very decided nerve involvement, it is possible that the long continued use of the telephone might have been a contributing factor. Few cases have been seen in which telephone operators have had a marked impairment of hearing apparently as a result of their occupation.

## "ARTHOX" OR "SULFIODOXYGENIA"

*To the Editor:*—Referring to the enclosed literature from the Standard Laboratories, will you please advise me whether you have any information regarding the preparation "Arthox" and oblige. M.D., Virginia.

*ANSWER:*—According to an advertising circular distributed by the Standard Laboratories, Inc., Boston, in 1935, Arthox is "a scientific medicinal formula," an "analgesic, specially prepared to aid in the relief of the muscular aches and pains of RHEUMATISM AND ARTHRITIS." The circular, which is apparently addressed to the public, gives no hint as to the composition of Arthox but does include numerous anonymous testimonials from physicians and laymen which, in the opinion of the Standard Laboratories, "attest convincingly what you may reasonably expect Arthox to do for you." The general character of these testimonials is well exemplified in the following verbatim copy of one of them:

New York .....Hospital  
December 20, 1934

Dr. .... has been kind enough to give me some Arthox from time to time for use in the clinic. We have had gratifying results in a number of cases in which other methods were ineffective.

(Signed) ....., M.D.

An examination of the advertising material which our correspondent received from Standard Laboratories, Inc., in 1936 indicates that Arthox—now embellished with the high sounding but meaningless synonym "Sulfiodoxygenia"—is sold "on physicians' prescription only." In other words, the "patent" medicine of 1935 becomes an "ethical" specialty of 1936! What are the ingredients of this "most valuable arthritis medicine" which some physicians apparently have taken seriously enough to enable the promoters to state that "additional research work" is being done in various places "including two of Boston's leading hospitals"? The constituents, according to information given by the manufacturer in 1935, are alcohol 2 per cent, Burnham's Soluble Iodine, anise, sassafras, glycyrrhiza, sarsaparilla, methyl salicylate and sodium salicylate! Though this statement includes no information as to the amounts of iodine and salicylate in the mixture, one would probably be justified in assuming that the preparation owes whatever effect it may have in arthritis to the presence of salicylates and, possibly, to the iodine. Apparently the promoters of Arthox (also called "Sulfiodoxygenia") and, sadly enough, some physicians too, are of the opinion that such medication possesses enhanced value when it masquerades under some such title as "Arthox" or "Sulfiodoxygenia." Incidentally, Burnham's Soluble Iodine, one of the claimed constituents of Arthox, is the subject of an unfavorable report by the Council on Pharmacy and Chemistry appearing in *THE JOURNAL*, July 1, 1933, page 33.

## PSORIASIS

*To the Editor:*—I will appreciate such information as you can give me concerning the treatment of psoriasis by the injection of an emulsion prepared from the scales of the lesions on the individual. I am unable to find much information about this.

M.D., Nebraska.

*ANSWER:*—Sutherland Campbell and Kendal Frost, in a preliminary report on a new form of therapy for psoriasis (*Arch. Dermat. & Syph.* 22:685 [Oct.] 1930) detailed observations on fifteen patients with psoriasis who were treated by intramuscular injections of a suspension of the patient's own finely ground psoriatic scales in alcohol. When possible, approximately 0.2 Gm. of psoriatic scales to 20 cc. of pure alcohol was used. The dose employed varied from 1 to 4 cc., the average dose being 1.5 cc., and the injections were given at intervals of three or four days. No untoward local or general reactions were noted. All patients responded to the therapy in varying degrees. The following objective changes were noted:

1. The scales became thinner and less adherent.
  2. The center of the lesions became pale.
  3. The last stage showed a smooth, slightly discolored area corresponding in size to the original lesion, with a few discrete lesions at the margins. The latter finally disappeared.
- Marcozzi (*Gior. ital. di dermat. e sif.* 74:441 [April] 1933) reported on the treatment of ten patients by this method, six

board to accept the surrender. With this contention, however, the Supreme Court did not agree. The fact that the license was surrendered, the court said, after the charges were filed and after evidence had been heard, was evidence from which the board could well infer that the dentist was guilty as charged. The court could not see how the order of revocation could in any manner constitute a refusal by the board to accept the surrender of the dentist's license. Furthermore, continued the court, since the record showed that the dentist voluntarily surrendered his license, he was not in a position to question the constitutionality of the dental practice act. The action of the superior court in dismissing the dentist's appeal was affirmed.—*East v. Carr (Ind.)*, 1 N. E. (2d) 1004.

### CENTRAL SOCIETY FOR CLINICAL RESEARCH

*Ninth Annual Meeting, Held in Chicago, Nov. 6 and 7, 1936*

The President, DR. FRED M. SMITH, Iowa City, in the Chair

(Continued from page 504)

#### The Alimentary Elimination of Normally Ingested Lead

DR. ROBERT A. KEHOE, Cincinnati: A study of normal human subjects has shown that the gross alimentary output of lead over a period of months is substantially equivalent to the gross lead intake in food and drink. The data of daily observations have been studied to determine the proportion of ingested lead which passes through the alimentary tract unabsorbed, and the proportion which is absorbed and subsequently excreted. The alimentary lead output and intake are strongly correlated over four day periods. Thus it is apparent that there is no prolonged delay in the elimination of the lead, and it might be supposed that the greater portion of the ingested lead simply traverses the alimentary tract. A relationship between the degree of absorption and the alimentary emptying time is suggested by the results on several subjects.

#### Response of Normal and Diabetes Insipidus Subjects to the Ingestion of Water

DRS. THOMAS FINDLEY JR. and H. L. WHITE, St. Louis: Verney has assumed that the polyurias of diabetes insipidus, of the perfused isolated kidney and of water diuresis are all due to diminished concentration of "pitressin" in the blood. Peroral administration of water to the intact normal mammal produces diuresis only after a definite interval of about one hour, during which time the blood pitressin content is falling below its threshold level in response to the stimulus of blood electrolyte dilution accompanying the absorption of water. If this theory is true, the diabetes insipidus subject should exhibit diuresis much sooner after drinking water because he has little or no pitressin in his blood to begin with. Eight experiments on three normal subjects show that the maximum dilution of blood electrolytes, as determined by the serum specific conductivity, precedes the peak of diuresis by about thirty-seven minutes. Similar studies on two diabetes insipidus subjects show a similar blood dilution after the ingestion of water but, contrary to

expectations, no diuresis curve was obtained. In view of the fact that no time interval could be established between the peaks of hydremia and of diuresis, no evidence either for or against Verney's theory was obtained; but the capacity of the diabetes insipidus subject to retain extra water for as long as eight hours is a little appreciated phenomenon and has important bearings on the mechanism of urine formation.

#### Excretion of Hormone-like Substances in the Urine

T. F. GALLAGHER, PH.D., A. T. KENYON, M.D., D. H. PETERSON, R. I. DORFMAN, PH.D., and F. C. KOCH, PH.D., Chicago: Benzene extracts of acidified urine were assayed on capons and castrated rats for their comb-growth stimulating and estrogenic properties. The normal male excretes from 13 to 79 international capon units of androgen and the equivalent of from 3 to 29 micrograms of theelin (estrone) daily, without evidence of cyclic change in continuous studies over six weeks periods. The normale female excretes from 13 to 50 international capon units of androgen and the equivalents of from 3 to 60 micrograms of theelin daily, the latter showing two intermenstrual peaks. One woman with adrenal virilism excreted 480 capon units of androgen daily, while fourteen other virile women showed from low to slightly high values.

#### Therapeutic Value of Convalescent Serum in Scarlet Fever

DRS. MAX FOX and MAURICE HARDGROVE, Milwaukee: A comparative study was made of 1,028 patients with scarlet fever; 139 who received scarlet fever antitoxin, 589 who received convalescent serum, and 300 who were untreated. All except 294 who were treated with convalescent serum in the home were in an isolation hospital. The majority of the cases of the home group were of moderate severity, while those of the hospital group were severe and often complicated. The sex and average age incidences were approximately the same. The average length of time after treatment until normal temperature was reached in the convalescent serum group was about one-half that of the antitoxin group. The average twelve hour fall of temperature in the serum group was 3.5 degree (hospital) and 3.4 degree (home) as opposed to 2.1 degree in the antitoxin group. In 68.4 per cent of the home group satisfactory response was shown if the serum was given within a three-day period, and in 14.9 per cent when given later than three days after the onset of the illness (83 1/3 per cent). In the hospital group a satisfactory response was obtained after convalescent serum in 90 per cent, and in 60 per cent when antitoxin was used. Complications occurred in 35 per cent of the cases after the use of antitoxin and in 16 per cent (hospital) and 12 per cent (home) of the convalescent serum groups. The incidence of reactions after convalescent serum was 1 per cent, as opposed to 35 per cent after antitoxin. Deaths occurred less frequently in the home group.

#### DISCUSSION

DR. MAX FOX, Milwaukee: There were eight deaths reported at the Isolation Hospital from among 295 patients, all of whom received convalescent serum. These patients were all admitted to the hospital from five to thirteen days after the diagnosis had been made and presented complications. They received from 20 to 120 cc. of convalescent serum. Convalescent serum, to be effective, must be given early and in large doses. If complications have already occurred, the convalescent serum may be of no help. In addition to convalescent serum, these patients were treated with intravenous therapy and specific and nonspecific immunotransfusions. There were available a number of post-scarlet fever patients properly typed whose blood could be used in an emergency; with the advent of convalescent serum we ceased to use these donors except for cases of this serious type. About 20 per cent of the cases treated at the Isolation Hospital fell into this group presenting complications or marked toxemia. Approximately 80 per cent were mild cases and received only general care. It is obvious that the clinician must be able to evaluate the cases with which he is confronted and must know which are the cases in which complications are likely to develop. For the general practitioner I recommend that convalescent serum be used in most cases. I take this opportunity of presenting a series of cases seen in consultation in the city of Milwaukee during an epidemic of scarlet fever. In this series there were eleven instances in

purgative dose of magnesium sulfate should be given and the treatment repeated about once a week until all the worms are destroyed. Thymol in doses of from 1 to 3 Gm. is a competitor. Carbon tetrachloride in doses not exceeding 3 cc. is also recommended and is considered by some as superior to the other two.

#### TRANSMISSION OF SYPHILIS

*To the Editor:*—A white woman, aged 25, is afflicted with heredo-syphilis. In January she sought treatment for a repeated attack of interstitial keratitis. Her Wassermann reaction was 4 plus. I started her on a bismuth compound; then she had a course of neosarsphenamine and is now on her second course of bismuth. The eye condition has cleared up nicely. The Wassermann reaction is still 4 plus. She is a splendid type of individual, quite intelligent and is aware of her condition. She wants to marry and is anxious to know what the possibilities are for transmission to her prospective husband and any possible child. She wants to get married this summer. Should she wait till she gets more treatment? She is quite aware that lifelong observation and intermittent treatment are necessary for the proper care of her disease. Please omit name and address.

M.D., Pennsylvania.

*ANSWER:*—This patient with congenital syphilis may marry at any time she likes without any risk of transmitting syphilis to her prospective husband. So far as the transmission of syphilis to a possible child is concerned, third generation syphilis does occur but is exceedingly rare. Of 118 children born to eighty-eight congenitally syphilitic mothers in one large clinic of the country, only eight of the children themselves had congenital syphilis. Even these chances may be lessened by adequate treatment of the mother during the course of her pregnancy.

#### TREATMENT OF SYPHILIS

*To the Editor:*—A man, aged 25, had a chancre in 1914 for which he received six injections of arsphenamine and was given mercury and iodides by mouth for several months. The four plus Wassermann reaction was changed to negative. He received no further treatment. In 1926 he had a severe attack of coronary thrombosis from which he recovered in about three months. In 1932 he had a similar but milder attack. He has been well since then. Now for the first time he admits a syphilitic history. The Wassermann reaction is one plus. The electrocardiogram shows evidence of myocardial disease. How much antisyphilitic treatment should be administered now?

M.D., New York.

*ANSWER:*—Coronary occlusion is rarely due to syphilitic heart disease. The slight degree of positivity in the complement fixation test is of no value in estimating the activity or lack of it of syphilitic infection of twenty-two years ago. If the patient has no physical evidence of syphilis, it would be wisest to withhold antisyphilitic treatment altogether. If physical evidence of syphilis is present, either in the form of syphilitic aortitis associated with what is almost surely arteriosclerotic heart disease or of neurosyphilis, antisyphilitic treatment might perhaps be given, although no definite opinion could be offered as to its type without further knowledge of the physical evidence of syphilis, if any, that may be present. Under no circumstances should the patient now be treated merely because of his weakly positive Wassermann reaction. The arsenical drugs are relatively contraindicated in a patient with myocardial damage of this degree.

#### INJECTION TREATMENT OF BURSAL CYSTS—NEURITIS

*To the Editor:*—I noted what you had to say in Queries and Minor Notes in *THE JOURNAL*, June 13, relative to the treatment of hydrocele with 5 per cent sodium morrhuate and wondered whether the same treatment is applicable to bursal cysts, especially in the popliteal space. Also kindly suggest treatment that will cure neuritis of the arm and hand (subacute).

SHERMAN R. WANTZ, M.D., Baltimore.

*ANSWER:*—Bursae in general are amenable to the injection treatment with 5 per cent sodium morrhuate. Popliteal bursae may widely communicate with the knee joint and their injection may produce a marked inflammatory reaction of the knee. The bursae of the hamstring muscles may be readily injected.

The treatment of neuritis of the arm and hand depends on the thorough investigation of its cause. Traumatic neuritis is caused by pressure of a cervical rib, arthritis of the spine, subdeltoid bursae, old injuries to the shoulder or brachial plexus. Infectious or toxic neuritis may be caused by influenza, typhoid, lead, arsenic, alcohol or carbon monoxide, to mention only the most frequent offenders, as there are many others. Possible foci in the teeth, tonsils, prostate and cervix must be investigated. Rheumatic nodules in the muscles, fibrositis, often simulate brachial neuritis. Symptomatic relief is afforded by salicylates, heat and abduction of the arm in an airplane splint.

#### EMOTIONAL UPSET PRECIPITATING HYPERTHYROIDISM

*To the Editor:*—Can a recurrence of acute hyperthyroidism in a case in which there have been no symptoms since thyroidectomy two years previous be precipitated by an emotional upset associated with a trauma? Please omit name.

M.D., New York.

*ANSWER:*—It is generally believed that an emotional upset associated with trauma may precipitate hyperthyroidism. If this concept is correct, it is also quite probable that an emotional upset associated with trauma might precipitate a recurrence of hyperthyroidism. However, there is no evidence obtainable that permits of drawing a definite conclusion in an individual case.

#### OPERATION ON LACRIMAL SAC IN INFANT

*To the Editor:*—I should like to have your version of the best treatment for an infected lacrimal sac, in a child 16 months old, the condition having persisted since birth; the nasal duct is open. What is the general impression regarding removal of the sac at such an early age? Please omit name.

M.D., British Columbia.

*ANSWER:*—The infected tear sac of an infant of 16 months should be removed through the external route. The nasal drainage operations used in adults are scarcely applicable, the nasal spaces in an infant are so small.

#### HAGEDORN-JENSEN METHOD OF ESTIMATING BLOOD SUGAR

*To the Editor:*—With respect to the note on page 2075 of the Dec. 19, 1936, issue of *THE JOURNAL*, Dr. Selsam is correct in her criticism of the "standardization" as published in the October 24 issue of *THE JOURNAL*, having to do with the Hagedorn-Jensen method of determining the blood sugar.

Thiosulfate solutions cannot be standardized against iodide solutions for a number of reasons. Two are that the end products of a thiosulfate-iodine reaction are a tetrathionate and an iodide, and that starch-iodide blue appears only in the presence of hydriodic acid or a soluble iodide. These reactions are in no wise matters of feeling but have been known, demonstrated quantitatively and taught to sophomore students of quantitative analysis for many decades. They may be found, fully described, in any standard work in that field, of which Treadwell and Hall's *Analytical Chemistry* is representative.

An infinitely preferable way of standardization of thiosulfate solutions is described in the sixth edition of Talbot's *Quantitative Analysis* on pages 78-80, using bromate, copper or arsenous oxide as reference standards rather than the metastable iodate. Use of these methods will make the final analysis of the blood specimen more nearly approach a determination rather than an estimation.

L. F. PIERCE, Ph.D., Los Angeles.

#### EFFECT OF STERILIZATION

*To the Editor:*—In the Dec. 5, 1936, issue of *THE JOURNAL*, on page 1912, there is an inquiry by a physician in New York regarding the effect of sterilization on epilepsy. In my experience I have found definite benefit in the treatment of epilepsy associated with menstruation by x-ray suppression of the menstrual function. In the *American Journal of Obstetrics and Gynecology* (26:116 [July] 1933) I reported on the result of treatment in just such a case as described by your correspondent, with excellent results. Recently numerous workers have shown a definite relationship between menstrual function and mental disturbances; x-ray therapy has been of distinct help in such conditions. In cases of epilepsy associated with menstrual function, it may be readily benefited by x-ray suppression of the menses. The question as to temporary or permanent sterilization rests on several factors, not the least important being the age of the patient. In most instances x-ray sterilization in women under 30 years of age is not permanent in effect.

IRA I. KAPLAN, M.D., New York.

#### HYPERPERISTALSIS WITH BORBORGYSMUS

*To the Editor:*—On page 320 of the January 23 issue of *THE JOURNAL*, in Queries and Minor Notes, is a question as to the possible etiology of hyperperistalsis with borborgymsus. Having seen one such symptom complex in a patient with proved brucellosis, whose symptoms disappeared under vaccine therapy, I would like to suggest the advisability of a blood agglutination test, intradermal test and perhaps an opsonocytophagic index test to rule out possible chronic, subclinical brucellosis.

HAROLD J. HARRIS, M.D., New York.

#### X-RAY THERAPY IN OSTEOMYELITIS

*To the Editor:*—On page 1988 of the Dec. 12, 1936, issue of *THE JOURNAL* I note your answer to a request for suggestions as to treatment for chronic osteomyelitis and was sorry that you did not mention x-ray therapy. I have found x-ray therapy very successful in my practice and believe that its advantages should be better known. In my experience surgery sometimes is followed by an acute exacerbation of the disease, and this is especially true in cases of osteomyelitis of the femur.

WILLIAM A. EVANS, M.D., Detroit.

hypotension. The man was 63 years old, with characteristic manifestations of that syndrome. He has been taking the drug for six months without any unfavorable effects so far as we can observe except a tendency to insomnia, which can be controlled with barbiturates. The dose has been high, as much as 150 mg. a day, especially in hot weather. The patient preferred benzedrine to ephedrine because it made him less tremulous, induced less insomnia and was perhaps somewhat more effective in dispelling his weakness. The hypotension was more easily and effectively controlled with benzedrine than with ephedrine.

DR. LOUIS LEITER, Chicago: I should like to know whether the authors have had any experience with this drug in muscular dystrophies.

DR. DWIGHT L. WILBUR, Rochester, Minn.: In answer to Dr. Keeton's question, the only observations on gastro-intestinal function we have made have been subjective ones. One of the most remarkable subjective changes is loss of consciousness of abdominal organs. Meyerson has demonstrated that benzedrine relieves spasm of the gastro-intestinal tract, and he has used the drug as a method of relieving spasm during roentgenologic study of patients. Dr. Katz had mentioned the fact that Dr. Nathanson of St. Paul has done considerable work on the effects of benzedrine in exhausted patients. This work served as an inspiration for our observations. I believe that Dr. Nathanson is in a better position than we are to discuss the effects of benzedrine used daily over a considerable period. Dr. Shapiro emphasized the fact that increase in pulse rate may follow administration of benzedrine. We have made similar observations in many cases, especially in patients who are nervous and already stimulated. Dr. Korn spoke about the effect of the drug in orthostatic hypotension. In one case we have observed that a more satisfactory result was obtained than with ephedrine. In answer to Dr. Leiter's question, we have not observed the effect of benzedrine in muscular dystrophy. I should like to emphasize the fact that benzedrine is a stimulant, that its effect is temporary, and that it therefore probably does not fundamentally and permanently alter a psychiatric disorder or a state of chronic exhaustion or neurosis.

#### General Edema of Indeterminate Etiology

DRS. MELVIN W. BINGER and NORMAN M. KEITH, Rochester, Minn.: Three selected cases with edema of obscure etiology were studied. It is interesting that in these cases there was a low serum protein concentration, all below 5 Gm. per hundred cubic centimeters and one as low as 2.7 Gm., yet there was no albumin in the urine. No gross evidence of liver disease was found. Basal metabolic rates, liver functional tests, blood chemistry and renal functional studies were carried out. One case came to necropsy with the outstanding finding of pancreatic degeneration. These cases were treated with high protein, low salt and low fluid diet, and potassium nitrate, from 8 to 12 Gm. daily, was given. In all cases the edema was controlled.

#### DISCUSSION

DR. JOHN TUCKER, Cleveland: I should like to ask the authors whether they have given their patients a thorough trial with massive doses of yeast extract. I have found that a certain group of patients with edema, in whom the usual causes of fluid retention have been ruled out, improve markedly with adequate amounts of vitamin B complex. It would appear that such patients are suffering with an atypical form of wet beriberi.

DR. MELVIN W. BINGER, Rochester, Minn.: Two of these patients were on a high vitamin diet. The other patients had been on a general diet with plenty of fruits and vegetables. There was no evidence of lack of vitamin.

#### Study of the Erythrocyte Volume and the Proteins of the Blood Serum

DR. FRANK H. BETHELL, Ann Arbor, Mich.: The mean corpuscular volume varies normally between 86 and 96 cubic microns, according to our observations with the Wintrobe technic. Deviations from this range are usually considered to denote developmental abnormality, the shift to large or small red blood cells occurring in the bone marrow. Such is the case of the macrocytosis of pernicious anemia and the micro-

cytosis of iron deficiency anemias. However, alterations of erythrocyte size may also depend on changes in the environment of the circulating red blood cells. An appreciable decrease in the serum protein is accompanied by red blood cells of increased volume. A swelling of the cells apparently occurs, which is related specifically to the albumin content of the serum and is not a simple osmotic phenomenon. Instances of macrocytosis accompanying cirrhosis of the liver are often of the latter type and are related to decrease of the serum albumin with reduction of the albumin-globulin ratio. Consequently, with certain limitations, determination of the average erythrocyte volume may give a clue to the functional efficiency of the liver in protein metabolism.

#### Further Studies on the Glomerular Function Test with Sodium Ferrocyanide

DR. EDWARD J. STIEGLITZ, Chicago: In 1934 Stieglitz and Knight published a preliminary report on sodium ferrocyanide excretion as a clinical test for glomerular function. This first clinical application of a ferrocyanide salt as a test substance was based on extensive experimental evidence that it is secreted solely by the glomeruli. Since then additional work has confirmed the first impression of the usefulness and physiologic soundness of this test procedure. A much larger series of normal control cases precisely defined the normal range of excretion. The new mean normal corresponds very closely with the 1934 figures. Additional studies in hypertensive arterial disease show that glomerular function is depressed more than tubular secretion. In hypertensive arterial disease there is an almost constant minute output of sodium ferrocyanide after the first hour; if the amount remaining in the body is used as the basis for the percentage excreted per hour the curve obtained is practically a horizontal line. This is taken as evidence that in hypertensive arterial disease the glomeruli are constantly active to the maximum of their depleted capacity. A close parallelism is found between the half hour output of sodium ferrocyanide and the maximum urinary specific gravity in the concentration test of Fishberg. I feel that the ferrocyanide test is quite sensitive to glomerular function change. Of necessity the full and thorough clinical evaluation of the test is still incomplete, but the present additional data contribute appreciably to our knowledge. Further studies are necessary and are thus being continued.

#### DISCUSSION

DR. WALTER S. PRIEST, Chicago: For the past year I have been interested in this work of Dr. Stieglitz, applying it to patients of the hypertensive group. In one patient, a woman of 60 with apparently early hypertension but not fixed hypertension because it responded to the ordinary methods of therapy, rest, and so on, it interested me to note that in the absence of demonstrable renal damage the ferrocyanide excretion was very slightly diminished. It raised the question in my mind whether this test might furnish a means of forecasting hypertensive states before they actually develop clinically, as indicated by rise in blood pressure or other symptoms. Perhaps the type of curve of the ferrocyanide excretion if corrected for the percentage remaining in the blood, as Dr. Stieglitz has shown, will give a clue as to the possible development of hypertension in individuals approaching the age at which we begin to look for cardiovascular disease. This test might be used as a routine in connection with periodic examination. I think that the test deserves further study before it can be properly evaluated.

DR. HAROLD C. HABEIN, Rochester, Minn.: I am glad to see that Dr. Stieglitz as well as others is continuing the study of sodium ferrocyanide as a test of renal function. The test is based on sound physiologic principles, and as time goes on further study and experience will make it possible to evaluate the test. Baker and I carried out studies with sodium ferrocyanide as a test of renal function in cases of urinary obstruction, for the first time so far as I know. Our studies were not carried out on a large group of patients, as the test has to be discontinued because of pain in the urethra in cases in which an inlying urethral catheter has been placed. Our study did, however, include ten patients and the results of our study would indicate that the sodium ferrocyanide test correlates very closely with other tests of renal function. From our study we

## Book Notices

**Starling's Principles of Human Physiology.** Edited and revised by C. Lovatt Evans, D.Sc., F.R.C.P., F.R.S., Jodrell Professor of Physiology in University College, London. The Chapters on the Central Nervous System and Sense Organs revised by H. Hartridge, M.A., M.D., Sc.D., Professor of Physiology at St. Bartholomew's Medical College. Seventh edition. Cloth. Price, \$8.75. Pp. 1,096, with 554 illustrations. Philadelphia: Lea & Febiger, 1936.

In subject matter this is one of the most complete single volume textbooks on the subject of physiology. However, this very fact constitutes its most serious defect as a textbook for medical students: there is a tendency to become lost in the mass of information. This defect is, however, to a considerable extent neutralized by the clear lucid style and logical treatment consistently followed throughout. Bibliographic references appear as footnotes on the same pages with citations. In addition, each chapter or special section carries at the end a list of references to monographs, special treatises and reviews. The value of some of the illustrations in proportion to the added cost of inclusion is questionable. For example, figure 450 is a full page cut of roentgenograms of the thorax at inspiration and expiration. Numerous consultations with students have revealed that this illustration means nothing to the average student. The same kind of evidence indicates that figures 232, 233 and 234, which are, respectively, a diagram of a recording spirometer, a respiration chamber for small animals and a Douglas bag, give little information not obtainable from figure 230, which is a schematic diagram of a Benedict respiration apparatus; yet the first three occupy most of two pages. However, illustrations of this type are not numerous. In view of the importance which vitamins and endocrines have assumed in physiology, the treatment of these general subjects is inadequate when compared to the space devoted to muscle and circulation, and there is too little correlation with the various phases of the "classic" pattern of physiology. On the other hand, the numerous functions of the liver are discussed in widely separated sections, so that only by exhaustive search with the aid of the index can the reader obtain a comprehensive view of liver physiology. There is thus too little attention given to the interrelations of its different rôles. However, it seems that it is too much to expect of any one author or even any two to be able to present adequately balanced treatment of every phase of the subject of physiology in face of the enormous volume of new information available every year that must be digested, correlated and condensed. The criticisms mentioned are therefore not criticisms of the work of the authors but of a condition. The wonder is that they have accomplished the task so well, for, despite its shortcomings, this textbook is one of the best available in any language.

**Undersøgelser over spæde Børns Ventrikelsekret, med særligt Henblik paa Pepsin-Løbeproblemet.** Af Bent Andersen. Paper. Pp. 94, with 4 illustrations. Copenhagen: Levin & Munksgaard, 1935.

The purpose of this work was chiefly to study the secretion of pepsin and rennin from the infant's stomach and to find out whether there was any evidence of the presence of rennin as an independent enzyme, different from pepsin. The study was carried out on infants from 8 to 40 weeks old, mostly convalescents in good condition. The gastric content was obtained by giving a test meal consisting of weak tea sweetened with saccharin. The meal was given in amounts adapted to the age of the infant, after a fast of at least six hours. The gastric content was obtained by aspiration forty minutes after the beginning of the meal. For the determination of peptic activity the amino nitrogen was determined at 0 and 120 minutes by the

method of Linderstrom-Lang. There was some evidence of increasing peptic activity as the infants grew older; in infants less than 21 weeks old the aspirated test meal contained an average of 27 "pepsin units" per cubic centimeter, while in the older infants the average was 42 "pepsin units" per cubic centimeter. In undiluted juice from four normal adults the same method gave the values 109, 210, 210 and 220 "pepsin units" per cubic centimeter. Taking into account the dilution by the test meal, the author concludes that the peptic activity of the gastric juice of the infant is of about the same magnitude as that of the adult. The rennin activity was determined by measuring the coagulation time of a suitable medium after the addition of gastric content and then calculating rennin activity by certain methods, which the author explains and justifies. The author was particularly interested in the ratio rennin: pepsin, which was found to be rather constant and of the same magnitude as in adults. This parallelism between the proteolytic and coagulating activity of gastric juice makes the author conclude that in the human being these functions are carried by one and the same enzyme and that there is not, as in the young calf, any independent coagulating enzyme (true rennin, the chymosin of Hammarsten). The work also contains studies of gastric acidity as measured by  $p_H$  and by titration. The literature on the various problems involved is extensively discussed.

**Johannes de Mirfeld of St. Bartholomew's, Smithfield: His Life and Works.** By Sir Percival Horton-Smith Hartley, C.V.O., M.A., M.D., Consulting Physician to St. Bartholomew's Hospital and to the Brompton Hospital, and Harold Richard Aldridge, M.A., Assistant Keeper in the Department of Manuscripts in the British Museum. Cloth. Price, \$4.50. Pp. 191, with 4 illustrations. Cambridge: University Press; New York: Macmillan Company, 1936.

The constant interest in the history of medicine which prevails brings us more and more volumes related to the predictions of some of the famous writers of the past. Johannes de Mirfeld was a medieval English medical writer credited by Sir Norman Moore with being the first genuine writer in medicine being in any way connected with St. Bartholomew's Hospital. He represented the priest type of physician. His most notable work as a medical writer was his *Breviarium Bartholomei*, an encyclopedia of contemporary medical knowledge with much superstitious and magical lore, such as charms and incantations. One of the most interesting chapters is that devoted to the signs of death. Also interesting are the pages dealing with the customs and ethics of medical practice.

**Undersøgelser over Refektion, med særligt Henblik paa Stivelsens Forhold.** With an English summary. Af Mogens Nathan. Paper. Pp. 160, with 9 illustrations. Copenhagen: Levin & Munksgaard, 1935.

The term refection refers to a condition that occasionally appears in experimental animals, mainly rats, fed on diets devoid of or poor in vitamin B and characterized by normal growth in spite of the insufficient nourishment and the excretion of bulky white feces containing large amounts of undigested starch. Refection may occur spontaneously or be produced by the feeding of feces from other relected animals. The stool contains characteristic gram-negative vibrios, amylase and starch which is not digested by ptyalin. The amount of starch in the stool is between 60 and 85 per cent in proportion to the amount of dry substance, and the utilization of starch is 57 to 92.4 per cent. Most of the starch escapes digestion in the small intestine. The possibilities are suggested that the reduced digestibility is due to changes in the starch grain itself and that the dyspepsia which results from the low or absent vitamin B content of the diet results in the indigestion of starch and favors the growth of vitamin B producing bacteria.

**The Life and Convictions of William Sydney Thayer, Physician.** By Edith Gittings Reid. Cloth. Price, \$2.50. Pp. 243, with 4 illustrations. New York, London & Toronto: Oxford University Press, 1936.

Dr. William Sydney Thayer, of New England stock, was noted as a physician, a humanist, a teacher and a scholar. He entered Harvard at 16 and, although suspended briefly because of a prank, returned and took his B.A. degree with the class of 1885 as Phi Beta Kappa. He then entered the Harvard Medical School, where he was especially interested in pathology. Postgraduate study in Berlin and in Vienna prepared him for the career finally offered to him as assistant to Osler. It was during his early period at Hopkins that he did his most important work as investigator. Miss Reid has prepared this

curve, and the statistical mode, mean, standard deviation, and variability determined. Since each increase in dosage of thyrotropic hormone administered causes a characteristic shift in the frequency curve, this procedure affords a quantitative method of determining the effects of the thyrotropic hormone on the guinea-pig thyroid gland.

## DISCUSSION

DR. CLARENCE F. G. BROWN, Chicago: I think those of us who clinically use these hormone compounds wonder whether these pharmaceutical preparations are real hormone preparations. This piece of work demonstrates in a clear, quantitative way that there is a genuine physiologic hormone at least in this preparation. Such work removes "folklore" and conjecture from hormone investigations and may lead to less pharmaceutical perversion.

DR. PAUL STARR, Chicago: We have been working with the thyrotropic hormone for several years. The present method of measuring thyrotropic dosage indicates that the amounts of this hormone used in experiments in previous years were greatly in excess of physiologic levels.

## The Normal Urinary Iodine of Man

DRS. GEORGE M. CURTIS and ITALO D. PUPPEL, Columbus, Ohio: Iodine is a normal constituent of human urine. Two hundred and twenty-seven determinations made on thirteen individuals without evidence of thyroid disease gave from 7 to 196 micrograms excreted for the twenty-four hour period, with averages of from 36 to 78 micrograms. The grand average was 51 micrograms for twenty-four hours.

The daily fluctuation in the excretion of iodine by the kidney may be great. This may be due to several normal variables. Even though the urinary excretion of iodine is influenced normally by many factors, wide variations are not representative of ordinary conditions. When the subject is kept on a constant regimen immediately preceding and during the period of study, the daily output is remarkably constant. The normal daily variation in the urinary iodine is accounted for chiefly by differences in the food iodine. The urinary iodine, normally, is derived to a lesser extent from the body metabolism.

The relation of age to iodine metabolism is as yet unknown. However, we observe that two boys of 8 years excreted 41 micrograms (average) of urinary iodine daily over a period of fifteen days; five men from 28 to 34 years of age excreted 50 micrograms (average) of urinary iodine daily over a period of sixty-nine days, and two men of 54 and 59 excreted 73 micrograms (average) of urinary iodine daily over a period of thirty days.

The average normal iodine excretion in central Ohio is less than that of normal man in the five goiter-free regions of Danzig, Berlin, Germany; Vik-i-Sogn, Norway; New Orleans, La., and Forte dei Marmi, Italy. It is a little less than that of the mildly goitrous region of Effingen, Switzerland. However, it is greater than that of the goitrous regions of Sandsvaer, Norway; Lwów, Poland, and Pécs, Hungary.

The normal human urinary excretion of iodine in five non-goitrous regions is approximately four times that in five goitrous regions. This difference in the urinary excretion of iodine is probably due to a difference in the available absorbable iodine in these different regions.

## DISCUSSION

DR. ITALO D. PUPPEL, Columbus, Ohio: These were all normal individuals living in various regions. We did not take into consideration any of the goiter patients.

## Plasma Hemorrhage

DR. HENRY N. HARKINS, Chicago: The importance of loss of whole blood in certain types of secondary shock is well recognized, but the etiologic rôle of loss of blood plasma-like fluid has not received the attention it deserves. The present paper discusses several well known examples of loss of plasma as well as several not considered heretofore. The presence and importance of plasma loss in the following conditions is considered: burns, intestinal manipulation, portal obstruction, release of an extremity constrictor, bile peritonitis, tissue autolysis in vivo, freezing, pneumoia, and externally strangulated colostomy loops.

## DISCUSSION

DR. C. J. LUNDY, Chicago: I should like to ask Dr. Harkins whether in his observations of these patients he used any method to prevent or overcome this plasma loss, such as injection of acacia solution or any hypertonic solution and if so, did it have any influence on the course of the patient's illness?

DR. HENRY N. HARKINS, Chicago: In these charts the distinction between experimental animals and patients is not always made clear. In a large number experimental animals were discussed. In the patient who was burned, blood transfusion was given and blood concentration seemed to go on independent of blood transfusion. I have given no blood plasma infusions to patients but have to experimental animals. The condition of the animals improved temporarily, but almost invariably they went on to eventual death, just as would have been expected if no plasma infusions had been given.

## Effect of Iron Deficiency in Pregnant Rats on the Young

DR. HOWARD L. ALT, Chicago: This problem was undertaken in order to throw further light on the relationship of maternal iron deficiency to iron deficiency in the infant. Albino rats receiving a whole milk powder diet did not develop anemia during a single pregnancy but had marked depletion of liver iron when studied twenty-one days post partum. During and after a second pregnancy, a moderate hypochromic anemia occurred. New-born rats from mildly deficient mothers had normal blood hemoglobin at birth but had marked depletion of the iron reserves. More severe iron deficiency in the mother resulted in a marked decrease in blood hemoglobin in the new-born. Administration of iron to the mother rats protected both the mothers and the young against iron deficiency. Supplements of copper to the mother's diet did not alter the results given. In iron deficient suckling rats the total hemoglobin formation during the first eighteen days of life was practically normal. From these experiments it seems likely that iron deficiency in pregnant women may result in a diminished iron content of the new-born. The observations of Strauss and of Josephs suggest that a normal iron reserve at birth is important for normal hemoglobin formation during the first year of life.

## DISCUSSION

DR. FRANK H. BETHELL, Ann Arbor, Mich.: I should like to ask whether these rats did well on the Klim diet. In my experience feeding rats such diets has not maintained their weight during pregnancy. With a mixed diet adjusted to a daily iron content of less than 0.3 mg. the mother rats' hemoglobin was decreased from 15 to about 10 Gm. per hundred cubic centimeters and the young developed such severe anemia during the first fourteen days of life that their hemoglobin was less than 3 Gm. per hundred cubic centimeters.

DR. ADOLPH SACHS, Omaha: In whole blood iron determinations of cord blood at birth the infant presents so-called polycythemia of the new-born. The whole blood iron takes a precipitous drop at once. Then there is another drop at the third month, which is hard to explain but which may be due to an iron depletion. Whole blood iron deficiencies occur in the late weeks of pregnancy of some mothers which can be avoided by administration of iron, which in turn aids the new-born. Dr. Alt found that addition of copper to the mother's diet in rats did not alter the results. This is also true in human beings because in a great many copper determinations in pregnant women I never found a copper deficiency.

DR. O. O. MEYER, Madison, Wis.: I wonder whether Dr. Alt administered so-called iron with copper, which is quite common, or whether it was copper-free iron.

DR. HOWARD L. ALT, Chicago: In answer to Dr. Bethell, I can say that adult rats which received an exclusive Klim diet for nine months remained in an excellent nutritional state. Also milk-fed animals were apparently able to undergo a normal pregnancy without difficulty. Undoubtedly, much depends on the nutritional condition of the rats used. The rats in our colony receive liver and vegetables once a week in addition to the stock diet. In answer to Dr. Meyer, no attempt was made to remove copper impurities from iron used for supplementary feedings. The preparation of ferric chloride used has been shown to contain insignificant amounts of copper.

(To be continued)

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Accident Insurance: Death from Veronal Poisoning.**—The defendant insurance company issued to the insured an insurance policy wherein it promised to pay certain benefits if death occurred as a result "of bodily injuries effected solely through external violent and accidental means." The insured died as the result of an overdose of veronal (barbital). He intended to take veronal but apparently did not intend to take a lethal dose. The trial court, in a suit to recover the benefits specified in the policy, gave judgment for the beneficiary. The supreme court, appellate term, New York, reversed that judgment and the beneficiary appealed to the supreme court, appellate division, New York.

This case, said the supreme court, falls within the category of such cases as *Gallagher v. Fidelity & Casualty Co.*, 148 N. Y. S. 1016, affirmed 117 N. E. 1067, and *Lewis v. Ocean Accident & Guarantee Corporation*, 120 N. E. 56. In the first case cited, the insured died from sunstroke and though he had intentionally exposed himself to the sun, it was held that his death had occurred through accidental means. In the second case, the deceased died from inflammation of the brain which resulted from infection occurring when the deceased had punctured a pimple with a contaminated instrument. In both cases, the insured had intended the act which resulted in death but an unusual and unexpected result followed. In construing the provisions of an insurance policy, the court said, its words should be judged in the light of the understanding of the average man. Ambiguities and uncertainties should be resolved against the company which drew the policy. So construed, the present policy, the court concluded, provided benefits for a death resulting from veronal poisoning where the insured intended to take veronal but accidentally took an overdose. The judgment of the trial court for the beneficiary was affirmed.—*Mansbacher v. Prudential Ins. Co. (N. Y.)*, 287 N. Y. S. 486.

**Accident Insurance: Death in Relation to Heart Disease, Trauma and Cerebral Hemorrhage.**—The Great Northern Life Insurance Company agreed to pay certain benefits if the insured died as a result of injury effected directly and exclusively of all other causes through external, violent and accidental means. No benefits were payable for the result of the injury if there was no "visible contusion, wound, or other marks or evidence of injury on the exterior of the body at the place of injury," or if the injury was "caused or contributed to directly or indirectly by . . . any pre-existing disease, infirmity, deformity or physical impairment. . . ." The insured died from a cerebral hemorrhage following an automobile accident. The insurance company refused to pay the benefits and the plaintiff, as beneficiary, brought suit. The trial court gave judgment for the plaintiff, and the insurance company appealed to the Supreme Court of Washington.

Several days prior to the accident, the insured, aged 56, underwent a physical examination, admittedly incomplete, which disclosed a low blood pressure, a probable pathologic coronary condition, a peptic ulcer, and a definite mitral valve heart murmur. The physician considered the condition of the insured serious and warned him against any undue strain or excitement. The accident occurred at a street intersection when the automobile driven by the insured collided with another car. Neither car overturned but both were considerably damaged. The driver of the other car upbraided the insured, who remained seated in his automobile, for the accident. The insured appeared in great physical distress, perspiration stood out on his face, and other evidences indicated that he was suffering intense pain. He complained of being sick, and asked that a discussion of the accident be postponed until he felt better. About a half hour later, the insured with difficulty got out of his car, took a few steps, and collapsed. His face became red, then turned purplish, and in a few minutes he died. An autopsy showed that death was due to an extensive cerebral hemorrhage, the blood clot that was removed being described as "large as one's

thumb." The insurance company contended that there was no causal connection whatever between the collision and the cerebral hemorrhage. Just prior to the collision, the company contended, the insured sustained a severe heart attack from which he partially recovered and that, when he left his automobile after the collision, he suffered a stroke of apoplexy due partly to the excitement engendered by the antagonistic attitude of the driver of the other car and partly by the exertion of getting out of the car in his then weakened physical condition.

The trial court instructed the jury that while the policy did not cover an injury in which there was no visible contusion, wound or other mark or evidence of injury on the exterior of the body, yet it did not necessarily follow that the injury must be external; that the visible signs and evidence might be such as indicated an internal injury; and that if the deceased became pale, sickly looking, showed signs of injury through perspiration or discoloration of his face at the time of or immediately after the collision, then the jury might find that there were visible marks or evidences of injury within the meaning of the terms of the policy. The words "visible mark or evidence of injury," said the Supreme Court, are not construed in the strict and narrow sense of a bruise, contusion, laceration or fracture, but in the broad sense of something that is discernible, perceptible, or evident on observation. This is the general rule and the rule that was laid down in *Horsfall v. Pacific Mutual Life Insurance Co.*, 32 Wash. 132, 72 P. 1028, in which case the court said:

It is also urged that the injuries causing death left no visible external mark, produced at the time of and by the accident, upon the body of deceased, and therefore the injury was one excepted from the policy. The evidence as stated above shows that immediately after the accident the deceased became deathly pale and sick, his hands and feet became cold, and the perspiration stood out on his face and hands. The next day after the accident his skin, which previously had been ruddy, became a bluish gray color, and remained so until his death. These, we think, were visible external marks, and sufficient to bring the case within the terms of the policy.

The trial court in the present case did not err, in the opinion of the Supreme Court, in instructing the jury as it did.

The insurance company further contended that the evidence as a whole was insufficient to sustain the verdict and judgment. The issues in the present case, said the court, were of such a nature that the jury was necessarily dependent on medical testimony in determining the cause of death. A medical witness for the plaintiff testified that death was caused by a cerebral hemorrhage resulting from the shock of collision, and that neither the coronary trouble nor the peptic ulcer had anything to do with the result. Another physician, a witness for the defense, testified that the cerebral hemorrhage did not occur until after the insured got out of the car thirty minutes after the collision, and that death was then almost instantaneous. In his opinion, the death was the result of a heart attack. The question thus presented was whether death resulted from cerebral hemorrhage induced by shock resulting from the accident or whether it resulted from coronary trouble. The testimony was clear cut and conflicting and presented a question for the jury to decide. It did decide that the death was caused by cerebral hemorrhage resulting from the accident, and the Supreme Court could find no reason for disagreeing with that finding. The judgment of the trial court was therefore affirmed.—*Hill v. Great Northern Life Ins. Co. (Wash.)*, 57 P. (2d) 405.

**Dental Practice Acts: Effect of Surrender of License in Revocation Proceedings.**—The Indiana state board of dental examiners instituted proceedings to revoke the license of the appellant to practice dentistry on the basis of charges filed with the board. The dentist appeared before the board and entered a plea of not guilty. After evidence had been heard, however, he voluntarily surrendered to the board his license. Thereafter the board revoked the license and the dentist appealed to the superior court of Lake County. The board filed a motion to dismiss the appeal on the ground that since the dentist had surrendered his license to practice dentistry in Indiana all questions raised in the appeal were moot questions. The superior court dismissed the appeal and the dentist then appealed to the Supreme Court of Indiana.

The dentist undertook to avoid the consequences incident to the surrender of his license by contending that the order of the board revoking his license constituted a refusal by the

posing circumstances surrounding the case at hand. If the pulse stops without warning during the induction of anesthesia, the cause is probably ventricular fibrillation. Respiration stops almost immediately after the ventricles fibrillate. Unless the anesthetist has his finger on the pulse constantly, fibrillation will be well advanced before it is recognized. The respiratory cessation will probably be mistaken for one of the frequent respiratory pauses occurring at this stage of anesthesia and death occurs almost before the anesthetist is aware that anything is wrong. Embolism, acute cardiac dilatation and apoplexy might be confused with ventricular fibrillation, although in none of these will the pulse go from normal to nothing between two heart beats. Artificial respiration with oxygen should be instituted immediately, because one can never be sure at the time that circulation has ceased entirely. If the abdomen is open at the time of fibrillation, circulation may be maintained by rhythmic compression of the heart between the anterior thoracic wall and the hand, through the diaphragm. Ventricular fibrillation is preeminently the condition in which direct cardiac massage is indicated. If the condition is recognized as soon as it occurs, opening the abdomen in order to prosecute this procedure is justifiable. Prevention lies in holding down the activity of the sympathetic nervous system and thus the output of epinephrine from the adrenals, and the avoidance of any external stimuli during the induction of anesthesia. Any preanesthetic medication that will prevent sympathetic hyperactivity is of value. Any disturbance of the patient during induction should be avoided. Beginning the preparation of the operative field or the surgical procedure itself before anesthesia is complete is dangerous. Since it is known that the danger zone is the second stage of anesthesia, anesthesia should be carried through this stage as rapidly as possible. The use of epinephrine in amounts sufficient to control bleeding during general anesthesia is to be condemned. Levy and others have shown that ventricular fibrillation is produced much more easily under anesthesia with chloroform than with other anesthetic agents. Aside from placing chloroform first and ethyl chloride possibly second, the authors cannot classify the other anesthetic drugs with relation to the frequency of occurrence of this phenomenon.

**Use of Acetyl Beta Methylcholine Chloride in Arthritis.**—Boyd and his co-workers used acetyl beta methylcholine by common ion transfer in the treatment of twenty-seven patients having arthritis. It was soon evident that certain less

advanced arthritic patients derived more benefit than the far advanced. Those with evident circulatory disturbances of the extremities—those with cool, pale, moist and often cyanotic hands and feet—seemed to gain most from the treatment. All patients had had considerable previous medical treatment along the usual lines without much evident improvement. Acetyl beta methylcholine is not useful in arthritic patients with peripheral arteriosclerosis nor is it feasible to treat patients with well distributed skin changes. It seemed most helpful in those who (1) show the earlier changes of the rheumatoid type, with cool, damp and cyanosed extremities, (2) have moderate hypertrophic changes with paresthesias and sensitivity to cold and (3) have sciatica or other manifestations of irritation of the spinal nerve roots as a result of spinal arthritis. Many patients showed not only a marked increase of the pulse volume wave in the member treated locally by common ion transfer but also minor increases in pulse volume wave in the opposite untreated extremity. The hands treated showed in eight of the fourteen patients an increased flexibility in function and usefulness in work. The group of failures in treatment were in general the elderly, far advanced rheumatoid arthritic patients with bone changes and fibrosis. Striking relief of pain was afforded some cases, but as a record of therapeutic achievement in this respect the results are only fair. The striking therapeutic effect in the group is the decreased fatigability and the increased endurance. This was noted consistently in almost all patients who absorbed the drug and took a sufficient number of treatments. No satisfactory measure of such fatigue has been proposed, though indirectly metabolic studies may help. The authors believe that, if fatigue can often be controlled, in many instances pain can be relieved, physical activity increased and the morale of these patients raised considerably. It is this effect of mecholyl that impressed them most.

**Vertigo in Brain Tumors.**—The observations of Spiegel and Alexander on brain tumors seem to corroborate the assumption of a representation of the labyrinth in the cerebral cortex, particularly in the temporal lobe. Parts of the frontal lobe, especially the centro-occipital region, must also be taken into consideration as a place at which vestibular and spinal impulses joined in the subcortex (cerebellum-ruber system) may enter. The conception that vertigo in brain tumors is only a general symptom of increased intracranial pressure seems to need a revision. In a large number of cases symptoms of choked labyrinth, hyperexcitability of this organ, differences in excitability between the two sides, nystagmus, diplopia and cerebellar disturbances are found, and the appearance of vertigo is explainable as due to these effects of increased intracranial pressure. Yet there remains a group of cases in which such an effect of

which other forms of streptococcal infection occurred among the contacts of scarlet fever patients. In one family the mother died of septicemia, probably puerperal, the grandmother had erysipelas and the grandchild scarlet fever. In another instance two children and the mother were brought into the Isolation Hospital with scarlet fever and the nurse who took care of them developed erysipelas. In another family the mother died of scarlet fever and the child developed the septic type of erysipelas. In another case at the County Hospital a nurse, who was in attendance on a child with scarlet fever, developed erysipelas. In the same hospital a nurse developed scarlet fever while in attendance on a case of erysipelas. In another instance a mother developed sore throat, the daughter developed scarlet fever and was attended by a nurse who developed erysipelas. There seems to be clinical evidence to show that there is a relationship between scarlet fever and erysipelas. I am certain from clinical observations that such cases as I have discussed do occur.

DR. W. O. THOMPSON, Chicago: From the mortality rates presented it would appear that a patient who develops scarlet fever is less likely to die if treated at home than if treated in the hospital. What is the reason for this? Do the patients who remain at home have the disease in a milder form than those who are confined to the hospital?

DR. ISADORE PILOT, Chicago: I want to say a word about the statements of the authors that scarlet fever and erysipelas may be due to the same hemolytic streptococcus. My work on septic sore throat, particularly in epidemic sore throat, and epidemic scarlet fever tends to show that scarlet fever and erysipelas are not related. For example, in the analysis of scarlet fever epidemics practically no cases of erysipelas have been reported, whereas in connection with septic sore throat the severe epidemics have shown the complication of erysipelas during convalescence. In my experience with scarlet fever patients and in the experience of contagious disease hospitals, erysipelas is a very unusual complication of scarlet fever, whereas in septic sore throat and tonsillitis with sinusitis, otitis media or enlarged glands, erysipelas is not an uncommon complication. I would therefore disagree with the authors that the etiologic organisms are identical in scarlet fever and erysipelas. The clinical results that may be obtained from convalescent serum and streptococcus serums may be misleading because there may be certain antibodies common to both scarlet and erysipelas streptococci.

DR. GEORGE F. DRICK, Chicago: My experience would agree with that of Dr. Pilot. I find that there is a distinction between these two diseases. If one takes a series of 500 people and immunizes them to erysipelas toxin they will still give a positive test to scarlet fever toxin. If another 500 are immunized with scarlet fever toxin, they will still give a positive skin test with erysipelas toxin. With erysipelas antitoxin and scarlet fever toxin there is no cross neutralization. With scarlet fever antitoxin and erysipelas toxin there is no cross neutralization. Cellulitis and dermatitis are seen when patients with scarlet fever are operated on, as for mastoiditis, but this is not called erysipelas. It is true in my experience, as in Dr. Pilot's, that erysipelas is commonly found in epidemics of sore throat, though not common in epidemics of scarlet fever. One is also unable to distinguish immunologically between the organism of septic sore throat and erysipelas. I think the important thing about the treatment of scarlet fever is that, as the authors mentioned, of using either convalescent serum or convalescent antitoxin to treat the case early. Unfortunately, doctors wait until the later stages to use either one at which time neither will produce a result.

DR. MAURICE HARDGROVE, Milwaukee: With reference to the low mortality in the home group, most of those cases were of mild or moderate severity and convalescent serum was administered early. The majority of the cases in the hospital group in which convalescent serum was given were severe or complicated and the serum was given later in the disease. It appears to be necessary to give convalescent serum early in the disease in order to lower the number of deaths and the incidence of complications.

DR. MAX FOX, Milwaukee: Possibly I did not make myself clear in one statement. I did not say that scarlet fever was complicating erysipelas or that we saw the two at any time

in the same individual. In reviewing the literature I found that it occurred once in 800 times. I did say that we found the two entities occurring in the same home under suspicious circumstances. These were clinical observations and as clinical observations the patients received convalescent pooled serum. Although we regard scarlet fever and erysipelas distinct clinically and etiologically, though caused by a hemolytic streptococcus, one cannot explain the cited cases otherwise than that they have occurred as the result of the same causative agent. It seems reasonable to anticipate that continued investigations on the problems of streptococcus differentiation will yield results supporting my clinical experience.

#### Clinical Experiments with Benzedrine Sulfate

DRS. EDGAR V. ALLEN, DWIGHT L. WILBUR and ALEXANDER R. McLEAN, Rochester, Minn.: Benzedrine sulfate is a sympathomimetic compound structurally related to ephedrine and epinephrine. Pharmacologic studies have indicated that this drug has a profound stimulating effect on the higher centers of the central nervous system. The effects of the drug administered orally in doses of from 10 to 20 mg. before breakfast, and frequently repeated at noon, have been studied in ninety-five patients without demonstrable significant organic disease whose chief complaints were melancholia, chronic fatigue and exhaustion, or nervousness. In from 75 to 80 per cent of patients with chronic exhaustion or depression the immediate results have been favorable and in some instances spectacular, leading to complete relief of exhaustion, exhilaration and increased capacity for mental and physical effort. In psychoneurotic patients, particularly those who are anxious, highly nervous and apparently stimulated, benzedrine had a less favorable effect. Of fifteen patients who had used the drug daily over a period of from two to three months, twelve have remained improved. In view of the possible unfavorable effects which have been reported by others, we feel that until further observation is made it is probably unwise to recommend the continuous use of benzedrine except for patients who are less than 60 years of age, who present no evidence of cardiovascular disease and who can be closely followed.

#### DISCUSSION

DR. ROBERT W. KEETON, Chicago: I wonder whether the authors made any observations on the gastro-intestinal tract with this drug.

DR. L. N. KATZ, Chicago: About a year and a half ago I had the good fortune of hearing about this drug from Dr. Nathanson, formerly of Minneapolis, who informed me that there was marked depression as an after-effect following the use of the drug. Were such after effects observed in this study?

DR. M. J. SHAPIRO, Minneapolis: I have been using benzedrine sulfate for somewhat more than a year. My first experience with the preparation was in the treatment of narcolepsy, in which benzedrine works admirably. My two narcoleptic patients are still well controlled with the same dose of the drug. With regard to the treatment of so-called chronic exhaustion, I have had a number of such patients on benzedrine for the past year. When I first began its use I prescribed doses that were too large, causing many of the patients to complain of nervousness, insomnia, rather marked loss of appetite, tachycardia, and often irregularity of the heart. On considerably smaller doses, I find that a favorable response is obtained without the disagreeable side-effects. The use of large doses over a period of time may cause a considerable rise in blood pressure. Most patients with chronic exhaustion can be controlled favorably with 5 mg. twice a day, preferably after breakfast and after lunch; giving benzedrine later in the day may cause insomnia. In some instances, good results were obtained with 2.5 mg. twice a day. As the authors have stated, one must use judgment in selecting the type of patient to be treated with benzedrine. The asthenic individual with a tendency to hypotension reacts most favorably. The hyperkinetic patient who exhausts himself with too much work should not be given this new drug; it may produce uncomfortable overstimulation. I have seen no ill effects from benzedrine after using it a year, particularly when small doses were given.

DR. H. M. KORNIS, Iowa City: Dr. W. L. Randall and I recently experimented with benzedrine in a case of orthostatic

posing circumstances surrounding the case at hand. If the pulse stops without warning during the induction of anesthesia, the cause is probably ventricular fibrillation. Respiration stops almost immediately after the ventricles fibrillate. Unless the anesthetist has his finger on the pulse constantly, fibrillation will be well advanced before it is recognized. The respiratory cessation will probably be mistaken for one of the frequent respiratory pauses occurring at this stage of anesthesia and death occurs almost before the anesthetist is aware that anything is wrong. Embolism, acute cardiac dilatation and apoplexy might be confused with ventricular fibrillation, although in none of these will the pulse go from normal to nothing between two heart beats. Artificial respiration with oxygen should be instituted immediately, because one can never be sure at the time that circulation has ceased entirely. If the abdomen is open at the time of fibrillation, circulation may be maintained by rhythmic compression of the heart between the anterior thoracic wall and the hand, through the diaphragm. Ventricular fibrillation is preeminently the condition in which direct cardiac massage is indicated. If the condition is recognized as soon as it occurs, opening the abdomen in order to prosecute this procedure is justifiable. Prevention lies in holding down the activity of the sympathetic nervous system and thus the output of epinephrine from the adrenals, and the avoidance of any external stimuli during the induction of anesthesia. Any preanesthetic medication that will prevent sympathetic hyperactivity is of value. Any disturbance of the patient during induction should be avoided. Beginning the preparation of the operative field or the surgical procedure itself before anesthesia is complete is dangerous. Since it is known that the danger zone is the second stage of anesthesia, anesthesia should be carried through this stage as rapidly as possible. The use of epinephrine in amounts sufficient to control bleeding during general anesthesia is to be condemned. Levy and others have shown that ventricular fibrillation is produced much more easily under anesthesia with chloroform than with other anesthetic agents. Aside from placing chloroform first and ethyl chloride possibly second, the authors cannot classify the other anesthetic drugs with relation to the frequency of occurrence of this phenomenon.

**Vertigo in Brain Tumors.**—The observations of Spiegel and Alexander on brain tumors seem to corroborate the assumption of a representation of the labyrinth in the cerebral cortex, particularly in the temporal lobe. Parts of the frontal lobe, especially the centro-occipital region, must also be taken into consideration as a place at which vestibular and spinal impulses joined in the subcortex (cerebellum-ruber system) may enter. The conception that vertigo in brain tumors is only a general symptom of increased intracranial pressure seems to need a revision. In a large number of cases symptoms of choked labyrinth, hyperexcitability of this organ, differences in excitability between the two sides, nystagmus, diplopia and cerebellar disturbances are found, and the appearance of vertigo is explainable as due to these effects of increased intracranial pressure. Yet there remains a group of cases in which such an effect of

also concluded that the sodium ferrocyanide test did not, from a practical standpoint, give us information which we could not get from other tests of renal function, especially the split phenolsulfonphthalein test.

DR. EDWARD J. STIEGLITZ, Chicago: An interesting case, which we did not report because of lack of time, has been observed for more than two years. The kidney function has been studied at intervals of about three months and gradual improvement in ferrocyanide output noted. We have seen no evidence whatever of intoxication from sodium ferrocyanide in the dosage used and advocated. It takes many years to evaluate any diagnostic test. It certainly took a long time before we felt any confidence in the phenolsulfonphthalein test. Recent work, many years after the introduction of the test, shows that there is much variation in the excretion of phenolsulfonphthalein from extrarenal factors. With sodium ferrocyanide the output appears to be wholly independent of the volume of urine secreted. This is in sharp contrast to the usual experience with phenolsulfonphthalein. The present report is but one step further and the work with this glomerular function test is still far from being complete. Extended studies are justified and necessary. They are being continued.

#### The Specific Dynamic Action of a Mixed Meal

DR. CYRIL M. MACBRYDE, St. Louis: Studies were begun four years ago on the relationship to the body weight of the rise in metabolism following a mixed meal. More than forty-five individuals have been followed through periods of weight gain and weight loss, both spontaneous and induced by diet, desiccated thyroid, dinitrophenol or insulin. Fifteen normal individuals were used for controls. In addition, more than thirty single determinations have been made on abnormally obese or thin persons. The specific dynamic action was found not to vary with the nutritional state but with the nutritional phase. Patients gaining weight showed lower specific dynamic action than the same patients when losing. With rapid weight loss the specific dynamic action tends to be very high. Pituitary and thyroid disease have no definite influence except as they change the nutritional phase.

#### Motor Involvement of Central Nervous System in Pellagrins

DRS. M. A. BLANKENHORN and TOM D. SPIES, Cincinnati: Pellagra is a clinical syndrome which characteristically affects the skin, gastro-intestinal tract and nervous system. In a given case of pellagra one or more of these systems may be involved. A diagnosis of pellagra can be made only if the person has characteristic pellagrous dermatitis or glossitis, or both. The lesions of the central nervous system are not visible during life, and the postmortem observations usually do not correlate well with the symptomatology of the disease. Motor involvement of the central nervous system in certain pellagrins has been described, but no controlled studies have been reported which show that the involvement of the motor portion of the central nervous system, like the accepted manifestations of the disease (dermatitis and glossitis), may also respond to anti-pellagic therapy. Three patients whom we observed had motor involvement of the central nervous system at a time when they had diagnostic pellagrous lesions. Two were adults who were addicted to alcohol; both had severe motor disturbances, characterized by rigidity, inability to walk, and slow choreiform movements; one resembling hemiplegia, the other spastic paraplegia. The third, a boy of 13 who did not drink alcohol, had paralysis of the four extremities which was suggestive of poliomyelitis. Following the administration of a high caloric, high protein diet and large amounts of powdered brewers' yeast, the pellagrous dermatitis disappeared and the motor function of the central nervous system was restored in all three cases.

#### DISCUSSION

DR. M. G. PETERMAN, Milwaukee: It seems to me that one of the cardinal symptoms of pellagra which has developed to any great extent is the loss of the deep tendon reflexes. Three years ago I saw a child, aged 7 years, who had elsewhere been put on a ketogenic diet and within six months developed a typical case of pellagra, with some anesthesia of the fingers, loss of the deep reflexes, some hesitation in gait and weakness in the legs. The child made an excellent recovery on 300 mg.

of dry brewers' yeast every day, but it took between eighteen months and two years to recover completely the loss of the patellar reflexes.

DR. TOM D. SPIES, Cincinnati: The case described by Dr. Peterman certainly seems to be one of pellagra associated with peripheral neuritis. I think that the peripheral neuritis in such cases responds to the administration of large amounts of a potent brewers' yeast. The three patients with involvement of the central nervous system were more severely diseased than the average pellagrin with peripheral nerve involvement.

#### Relation of Thyroid Gland to Hematopoiesis

DRS. J. DEWEY BISGARD and JOHN C. SHARPE, Omaha: This report presents complete blood studies in thirty-two totally thyroidectomized rabbits showing the development of the macrocytic anemia of myxedema and its response to thyroid feeding, liver extract and iron. This is controlled with the feeding of the same substances in thirty-five normal rabbits. Studies include daily reticulocyte counts and frequent hematocrit determinations.

#### DISCUSSION

DR. O. O. MEYER, Madison, Wis.: These results, I think confirm to some degree what we have appreciated about cretinism and myxedema. One point of interest was that the reticulocytes persisted at a high level, in one slide from 6 to 8 per cent. That differs from what we have found in thyroidectomy in rats. The reticulocytes normally were about 3 per cent, and a very significant decrease followed total thyroidectomy. One would expect an increase in reticulocytes following thyroid administration.

DR. J. DEWEY BISGARD, Omaha: We have shown the anemia and other signs of myxedema that developed in these total thyroidectomized rabbits. We have another group of thyroidectomized rabbits that were used for entirely different experimental purposes but do have some bearing on this problem. After these animals were totally thyroidectomized we transplanted the tissue removed at operation into the anterior chambers of both eyes, in some animals as an autogenous and in some as a heterogenous transplant. The transplanted tissue becomes attached to the iris and becomes vascularized because it gets its blood supply from the iris very promptly. Two things happened in these animals, and they can be divided into two or more groups according to the fate of the transplants. In one group the transplants remained vital and were vital up to the time the animals were killed, as long as ten months after transplantation. None of these animals developed either signs of myxedema or the anemia of myxedema, and so it appears that these transplants were actually functioning. In the other group the transplants at the time the animals were killed were found to have undergone complete necrosis. We found the thyroid tissue all gone and replaced by fibrous tissue. All in this group developed anemia and other signs of myxedema, but they developed these signs from twelve to sixteen weeks following total thyroidectomy, one or two months later than the group reported, the group that received no transplants. The delay in development of myxedema was due presumably to two causes: first, that the transplants had a short period of viability, and second, that the thyroid tissue which was transplanted carried with it a certain amount of thyroid principle that delayed the onset of myxedema.

#### Increase in Heights of Thyroid Cells as a Method of Thyrotropic Hormone Determination

DRS. PAUL STARR and RULON W. RAWSON, Chicago: Our object is to describe the application of micro measurements of the hyperplasia of the thyroid, induced by the thyrotropic hormone, with statistical analysis of these measurements, as a quantitative determination of the hormone present. Female guinea-pigs weighing 200 Gm. after three daily subcutaneous injections of quantities ranging from 0.0025 to 0.02 cc. of antuitrin T were examined post mortem and the thyroids removed on the fourth day. Paraffin sections stained with hematoxylin and eosin were studied under oil immersion. The height of the representative cell of each of 200 acini, selected according to a uniform system, was determined with an ocular micrometer. The 200 measurements were graphed in a frequency

conduction time and lowest in those with shortened bone conduction time. The differences are statistically significant. The effect of age on the acuity of hearing by bone conduction appears to be the most noteworthy finding. Prolonged bone conduction time in all probability represents the upper "tail" of the frequency distribution of the normal variation. The fact that the persons with such bone conduction were the youngest, on the average, may be regarded as confirming the hypothesis that acuity of hearing by bone conduction is associated with some factor or factors other than the condition of cochlear nerve and end organ.

**Tuberculosis of Liver.**—Rosenkranz and Howard encountered three cases of tuberculosis of the bile ducts in their necropsy service. Necropsy of the first patient revealed that the man died of an advanced tuberculosis of the spine, with a milary spread into the inner organs complicated by tuberculous abscesses along the intrahepatic bile ducts. The second patient was a young native Filipino in whom, without signs of pulmonary infection, tuberculosis of the bone developed which was complicated by tuberculosis of the bile ducts and of the liver. The site of the primary infection must be assumed to have been the intestine. The last case was one of typical progressive pulmonary and extensive intestinal tuberculosis with caseation of the mesenteric, peribronchial and periportal lymph nodes, complicated by a secondary tuberculous cholangitis with abscess formation. The microscopic picture of the liver in these cases shows a rupture of caseous tubercles into the bile ducts from the periportal tissue. The excretion of virulent tubercle bacilli with the bile is always due to microscopic ruptures of this kind. Development of tubular tuberculosis of the liver is favored by an early generalized spread of the primary infection, especially when the latter occurs in the intestine. This type of tuberculosis is usually found in young children and in races that do not have high resistance against infection by Koch's bacillus. Intestinal primary infection tends to spread easily and to retain virulent bacilli for a long time.

**Action of Sodium Chloride on Skin Necrosis.**—Rigdon treated nineteen rabbits intradermally in five areas on the right and on the left side with from 1.5 to 2.5 cc. of an 0.85 per cent (right) and a 5 per cent (left) solution of sodium chloride. Into each bleb made by the salt solution, from 0.1 to 0.2 cc. of staphylococcus toxin was injected at intervals varying from immediately to two hours. Sixteen rabbits showed a decrease in the extent of necrosis in the areas previously receiving the 5 per cent solution. The most pronounced degree of inhibition occurred when the interval between the injection of the 5 per cent solution and the injection of the toxin was from five minutes to one hour. The location of the necroses with regard to the points of toxin injection in the areas receiving the one concentration of sodium chloride was different from that in the areas receiving the other. In the areas treated with the 5 per cent sodium chloride solution, necrosis occurred at the sites of toxin injection and also frequently inferior to these points. The skin between these two necrotic regions was macroscopically normal.

**Ossification: Influence of Mineral Constituents of Bone.**—The results of Bisgard's investigation indicate that in experimental animals: 1. The synthetic salts of bone, calcium carbonate, calcium phosphate and magnesium phosphate have no influence on osteogenesis or ossification. In great concentration and in the presence of tissue not in itself osteogenic but recognized as ossifiable, these salts failed to give rise to the formation of bone, and in the presence of osteogenic tissue they appeared not to alter the normal course of ossification. 2. Bone, regardless of its viability, has a favorable influence on ossification. This was true of partially viable bone, boiled bone and bone ash. Transplants of the former invariably initiated ossification in the fibrous tissue surrounding them. This was true also of boiled bone, but to a much lesser degree, and, although it did not occur with the use of bone ash under similar circumstances, ossification did take place in transplants of fibrous tissue and epithelium from the bladder which were bathed in bone ash. Since bone was not formed in this type of transplant in the rabbit in mediums of either normal aqueous or bone salts, it is deduced that bone ash possesses some factor favorable to ossification which is not present in bone salts. It would seem likely, as suggested by Watt, that calcium as it exists in bone exists in a physiochemical or structural form more suitable for use in the process of ossification.

**Unusual Cartilaginous Tumor Formation of Skeleton.**—Freund reports four cases of cartilaginous tumor of the skeleton, which represent in part unusual forms of otherwise well known conditions (enchondroma, single osteochondroma and multiple cartilaginous exostoses) and in part an apparently rare form of a multiple intra-articular tumor formation which, to his knowledge, has not yet been described. There is one case of a true intra-articular osteochondroma, which developed in more than one joint on the basis of a peculiar hyperplastic change of joint cartilage and which had to be differentiated from similar formations as they develop typically in persons with hypertrophic arthritis and from other conditions usually considered neoplastic changes of the joint capsule, such as chondromatosis of the joints. Besides the cartilaginous component, a considerable amount of bony tissue was present. One is justified in speaking of the growth as a cartilaginous tumor, despite the fact that in some instances the bony component is prevalent, mainly because the cartilaginous portion represents the real active element in the tumor, the cellular proliferation of which results in the increase in size. The bony tissue replaces the cartilage; its significance is therefore merely secondary.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (\*) are abstracted below.

**Tremors of the New-Born.**—From a study of the laboratory data of infants with tremors or birth shock and children with tetany, Litchfield discovered that many of the minor disturbances might be dependent on an underlying calcium deficiency. In addition to the supplying of the full demand of the body for calcium, certain further therapy seemed necessary for the control of the common functional disturbances as represented in these cases. In considering the medication most appropriate for these patients, he found that a new chemical compound of calcium lactobionate and calcium bromide appeared to possess such properties as to make it especially suitable. This preparation is a crystalline double salt produced during the manufacture of polyhydroxymonocarboxylic acid by oxidizing lactobiose with calcium hypobromide in the presence of calcium hydroxide. The double salt may be crystallized directly from the solution. To test the therapeutic efficacy of this preparation, two reasonably comparable groups of infants were studied. The infants who received the new double salt in one-half teaspoonful doses twice daily showed a complete change in the clinical picture with a uniform increase in the calcium content of the blood, and all the symptoms disappeared in an average period of slightly less than seven days. Similarly good results were obtained with this new preparation in a group of older children who from birth had had manifestations of nervous disturbances.

**Serum Disease and Therapeutic Effect of Diphtheria Antitoxin.**—Davidsohn and Hunt studied forty patients with so-called immediate or accelerated serum reactions, 164 patients with ordinary serum reactions and ninety-seven patients without any serum reactions. No difference was noted in the therapeutic effect on the patients with ordinary serum disease and on those without any serum reactions. On the other hand, the therapeutic results were distinctly less satisfactory and the incidence of complications was considerably higher in the patients with immediate serum reactions.

**Bile Peritonitis in Infancy.**—Caulfield reports two cases of bile peritonitis in infants in whom successful surgical treatment was possible even after the disease has persisted for some time. Both the infants had been apparently normal for about three weeks, at the end of which time they manifested signs of biliary obstruction—jaundice and bile-stained urine in one patient and acholic stools in the other. In each instance the infant was brought to a physician not because of jaundice, vomiting or pain but because of swelling of the scrotum. The jaundice was intermittent. On admission there were signs of

a marked increase in intra-abdominal pressure—respiratory distress, pouting umbilicus, fluid in the scrotum and engorged superficial veins. The abdomen of each patient showed on percussion a shifting dullness. The temperatures were normal or subnormal. Both patients had acholic stools and their urine did not contain bile. The absence of bile pigments from both stools and urine, without jaundice, should immediately suggest that there is a rupture along the biliary tract and that bile is flowing freely into the peritoneal cavity. In both instances the disease was amenable to surgical treatment, in the first case actually and in the second theoretically. The first child recovered with a functionally perfect biliary tract after simple drainage in the region of the bile ducts. The surgeon suggested that the child may have had an accessory duct which functioned after operation, but his rapid recovery following simple drainage constitutes evidence very much against the existence of any extensive or serious abnormality. The second child had stenosis of the common duct, and at necropsy inspissated bile was found between the stenosis and the ampulla. Whether this inspissated bile was formed before or after the rupture is not known. There was a theoretical possibility of surgical repair, especially if an early diagnosis had been made. If repair of the ruptured common duct or anastomosis of the sac wall to the intestine had been technically difficult or impossible, perhaps a cholecystoduodenostomy with ties on the common duct or a drain to the region of the rupture might have saved the patient's life.

**Ventricular Fibrillation in Anesthesia.**—Guedel and Knoefel point out that ventricular fibrillation occurs without warning; it either passes in less than a minute or death results. The approach to a surgical operation and the induction of anesthesia provide favorable circumstances for its occurrence. The most likely time in anesthesia for the occurrence of ventricular fibrillation is in the stage of delirium immediately after consciousness is lost. It is most likely to occur in the periods of life when general physiologic activity is greatest; that is, between the ages of 5 and 30 years. Clinical recognition of the phenomenon depends largely on the appreciation of predis-

the following morning. For supper at 5:30 he is served with food containing as little water as possible. Such dry food includes meat, fish, egg, bread, butter, cheese and crackers. When the child is already in bed for the night and all his wants and requests have been attended to, he is given a sandwich containing about 5 Gm. of salt. The salt is given most effectively when combined with fat or meat abundant in binding tissue. Under such conditions the salt is absorbed gradually and the restraining influence on the discharge of urine is prolonged. Measured quantities of salt butter, ham, bacon, boned herring, boneless salt codfish, Swiss cheese, smoked salmon and salt can be used for the fillings. To make the herring or fish more palatable, chopped hard-boiled egg or raw scraped apple may be added. At the end of about two months of this regimen cereal, vegetables and some fruit were added gradually. This more liberal plan was continued for two months longer, after which the salt was decreased slowly. If bed wetting occurred on the reduction of the salt intake, it became necessary for a while to give a larger portion of a salty sandwich. In most cases the reduction of the salt intake was gradually accomplished without any recurrence of the nocturnal enuresis.

**Diminution of Spinal Fluid Sugar in Tuberculous Meningitis.**—Weichsel and Herzger observed the diagnostic value of spinal fluid sugar in cases of tuberculous meningitis. The method used for the examination of the spinal fluid sugar was that of Jensen and Hagedorn. A progressive diminution of the spinal fluid sugar was found from the time of first observation to the fatal termination of the cases. In this decline there is in many cases a slight increase about two weeks before death, and then a final drop of the sugar content. The authors feel that the diminution of the spinal fluid sugar is an early diagnostic sign, since in several cases the value of the sugar showed a decline from twenty-five to thirty days before the death of the patient. In most cases the decrease in the sugar content follows a rise in globulin and an increased cell count. Following the intraspinal injection of a 5 per cent solution of dextrose in children with tuberculous meningitis, a response in blood sugar was observed, which can be compared with that found after intramuscular injection or after absorption of sugar from the intestinal tract. The sugar content of the cerebrospinal fluid at the end of a spinal puncture gave almost the same value as at the beginning, and a repetition of the puncture after one hour usually gave no higher amounts. After an artificial increase of the blood sugar, the ratio between blood and spinal fluid sugar remained the same. The absolute augmentation of the dextrose in the cerebrospinal fluid was very low. The experiments tend to show that the chief cause of the diminution of sugar is not an increased glycolysis but rather a disturbance of the barrier between blood and spinal fluid.

**Effects of Drugs on Autonomic Nervous System.**—Freeman and Carmichael observed the reactions of blood pressure and pulse rate in twenty-four male subjects to the intra-

venous administration of epinephrine, atropine, physostigmine and ergotamine. The administration of all four drugs resulted in a significant rise in systolic blood pressure of varying intensity and duration. The diastolic blood pressure also underwent a significant increase with the exception of epinephrine, in which case pressor and depressor responses were so equally distributed that the net change was negligible. Epinephrine, atropine and physostigmine each resulted in a significant increase in pulse rate, while ergotamine caused a significant slowing of the heart rate. No significant relationship was found in the reaction of the systolic or diastolic pressure or pulse rate: to the magnitude of their control readings, to one another after the injection of a single drug or to one another in a comparison of the responses to several drugs. This lack of relationship was due to individual variability rather than to inconsistency of the basal blood pressure and pulse rate.

**Simple Method for Doing Nephropexy.**—McKenna believes that pain is the first indication for nephropexy. It may be acute, chronic or periodic. In carrying out his procedure he has the patient lie on the side with the leg next to the table flexed at a right angle and the upper leg straight. A V-shaped incision is made through the lumbar fascia with the apex at about the level of the ninth or tenth rib and the base in the middle of the twelfth rib. The flap should be just long enough to make implantation into the kidney parenchyma. The fascia, to make the implant, may be brought between the eleventh and twelfth ribs or it may be brought over the last rib with the implant directed into the kidney parenchyma. The incision into the kidney parenchyma is not more than 0.5 cm. deep and 1.5 cm. long. At this point partial decapsulation is done around the incision into the parenchyma. This permits the surgeon to fold the kidney capsule on either side of the incision so as to make a pad through which to pass the suture in order that there is no tearing or mutilation of the kidney parenchyma. One stitch is usually sufficient to make the fixation. The kidney is placed in position and the wound is closed in the ordinary way. The perinephric fat or fascia of Gerota is now brought up over the kidney to act as a temporary hammock during the patient's convalescence. The patient is placed in bed with the foot of the bed elevated about 6 inches and kept there for three weeks to allow for a better anastomosis between the fascia and the kidney itself. The purpose of the operation is to place the kidney in position so that there is a straight line between the kidney pelvis and the bladder. Incision of the kidney parenchyma has led to no appreciable difference in function.

**Infiltrating Carcinoma of Bladder.**—Colston and Leadbetter have made a study of ninety-eight cases of extensive infiltrating tumors of the bladder from both the clinical and the pathologic points of view. Of the ninety-eight cases, fifty-

pressure on the labyrinth or on the brain stem is absent. In these cases, at least, it seems not unreasonable to assume that the vertigo may appear as a local symptom of the cerebral cortex due to direct lesion (stimulation) of the aforementioned cerebral areas, or due to pressure on these foci by tumors in neighboring regions. In general it seems that tumors close to the sylvian fissure induce vertigo more easily than do tumors more distant from this fissure.

**Hyperparathyroidism in Siblings.**—The clinical, metabolic and roentgenologic observations associated with the classic type of von Recklinghausen's disease are illustrated by the two cases reported by Goldman and Smyth. Hypercalcemia was evident in both. Conversely, the phosphorus was lower than normal. One patient had renal calculi and the other did not, although the excessive urinary loss of calcium and phosphorus in both patients (a sister and a brother) would presumably favor the formation of stones. Perhaps the extent of the process in the first patient would suggest a disturbance of metabolism of longer standing, which would favor lithiasis. The transition from the hypercalcemia of hyperparathyroidism to the hypocalcemia of hypoparathyroidism was observed post-operatively in the second patient. It is important to meet the immediate reversal of function following parathyroidectomy by a diet low in phosphorus and high in calcium, which helps to guard against further depression of the calcium. While this is ordinarily accomplished by administration of calcium, the authors believe that a careful restriction of phosphorus is of additional benefit. Additional calcium was not given in the cases cited, as a minimal intake was desired to allow detection of the endogenous (endocrine) factors. The study illustrates the shift of the excretion of calcium from urine to stool, and the change to a positive balance. That this is a temporary phenomenon must be admitted, since follow up has shown no persistent tetany and no hypocalcemia. It is likely that further study might show a readjustment to that of the normal adult metabolism. An erroneous diagnosis of giant cell tumor was made roentgenologically in one and microscopically, after biopsy, in the other patient. Giant cell tumor is usually situated asymmetrically at the epiphyses of the long bones and is usually single rather than multiple. The giant cell variant of fibrous osteitis may occur in the shaft of the bone, subperiosteally or centrally, and is associated with generalized demineralization of the skeleton and altered calcium and phosphorus metabolism. This lesion is more likely to be multiple. If a small portion of surrounding bone proper is included in the biopsy, the histologic picture of fibrous osteitis should be evident enough to suggest hyperparathyroidism in cases of giant cell variant. The symptoms and signs in both patients disappeared rapidly following the removal of the parathyroid tumors, and a deposition of minerals in the skeleton took place within a short time. A markedly negative calcium balance became positive after parathyroidectomy, indicating that reconstruction of

the skeleton was taking place. In time, a normal negative balance may be expected to supersede this. The symptoms of easy fatigability underwent the most marked subjective improvement. The presence of malacic disease in two members of the same family does not necessarily point to a diagnosis of fragilitas ossium or to any other type of familial skeletal disturbance.

**Operation for Right-Sided Ulcerative Ileocolitis.**—To put the diseased colon at rest and to irrigate and cleanse it, Berg has carried out the following procedure in five cases: A left-sided transrectus incision is made extending 3 or 4 inches upward from the symphysis; the terminal ileum is identified and delivered out of the wound. The healthy sigmoid is similarly delivered into the abdominal wound. The healthy ileum, as near to the ileocecal valve as is possible, is cut completely across and its mesentery is divided. Both ends are closed by two or three tiers of sutures; an inner chromic catgut suture is made through all the coats, reinforced by one or two layers of interrupted linen or chromic catgut sutures. The proximal end of the ileum is joined to the lower sigmoid just above the peritoneal reflection by a side-to-side anastomosis. Several inches above this side-to-side anastomosis the sigmoid is cut completely across, the distal end is closed by a row of chromic catgut sutures reinforced by one or two layers of linen or catgut, and the proximal end is tied off with a heavy silk suture, thoroughly phenolized and brought out through the upper angle of the wound. The rest of the abdominal wound is closed in layers. The heavy silk suture around the proximal end of the sigmoid is left in situ for from forty-eight to seventy-two hours and then removed, leaving a fistula in the proximal end of the sigmoid. The fecal stream is thus entirely diverted into the lowermost sigmoid and rectum, and the fistula in the sigmoid permits the free drainage of the products of inflammation from the diseased colon. After from ten to fourteen days the colon is irrigated through the sigmoid fistula. The entire colon and the diseased portion of the ileum have been removed subsequently in two cases.

**Conduction Deafness.**—Ciocco discusses data on the acuity of hearing by bone conduction for 516 patients with a conductive type of impairment (acuity by bone conduction being better than that by air conduction). The data have been statistically analyzed to determine whether or not the acuity of hearing by bone conduction is related in any way to age, the appearance of the tympanic membrane, tinnitus, a history of familial deafness and the degree of impairment of hearing by air conduction. Prolonged bone conduction time was found in 26.7 per cent of the cases, normal bone conduction time in 66.1 per cent and shortened bone conduction time in 7.2 per cent. Those with prolonged bone conduction time were, on the average, the youngest; those with shortened bone conduction time were the oldest. On the average, the acuity of hearing by air conduction of persons with prolonged and with normal bone conduction time was similar and was more acute than in patients with shortened bone conduction time. A normal tympanic membrane was observed with greater relative frequency in persons with prolonged bone conduction time, while a perforated tympanic membrane was found relatively oftener in those with shortened bone conduction time. The incidence of tinnitus was practically the same for all groups. The incidence of a family history of deafness was highest in those with prolonged bone

**Ornithodoros Turicata: Possible Vector of Relapsing Fever.**—In late August and early September 1936 Davis and two assistants recovered approximately 2,000 specimens of *Ornithodoros turicata* in Clarke County, heretofore not known to occur in Kansas. The various stages of the tick were found in rodent burrows, in holes in sand and attached to cottontail rabbits, spermophiles, prairie dogs, prairie dog owls and terrapins. From a single sand hole which contained eleven terrapins (*Terrapene ornata*) 1,197 ticks were removed. Three strains of spirochetes were recovered from ticks collected from a prairie dog burrow, a sand hole and a cottontail rabbit burrow. The prairie dog burrow was located on a ranch at which a case of relapsing fever had occurred. It seems reasonable to believe that *Ornithodoros turicata* may be implicated in the transmission of relapsing fever in this area.

**Diphtheria Immunizations and Cases.**—Collins conveys the information on the history of artificial diphtheria immunizations obtained on 8,758 white families in 130 localities in eighteen states. The group makes a composite cross-section of the population of the United States. Considering the whole group, 43 per cent of children 9 years of age gave a history of an artificial diphtheria immunization; above this age the percentage declined until at from 20 to 24 years only 5 per cent gave such a history. About 7 per cent gave a history of an attack of diphtheria at this age period. Boys and girls show about the same percentages with a history of diphtheria immunization. Boys less than 10 years of age gave more histories of attacks than girls. In the Northeast and the South the percentages of persons with a history of diphtheria immunization were somewhat higher than in the North Central and Western regions. The South was also high in histories of attacks, but the Northeast was low. Histories of diphtheria immunization were as

frequent in rural as in urban places, but histories of diphtheria attacks were most frequent in large cities. The frequency of diphtheria immunizations of children of the preschool ages increases regularly with family income; in the school ages the frequency of immunizations does not show any consistent relation to income. The peak of diphtheria case incidence occurs at a younger age in the South than in the North. The peak of diphtheria mortality in the registration states occurs at 2 years of age. The maximal diphtheria case fatality occurs among infants less than 1 year of age.

**Insulin Therapy for Peptic Ulcer.**—Sperber employed insulin in the treatment of twenty patients with duodenal or peptic ulcers who received no relief from a dietary regimen. Early cases were relieved of all symptoms and, while observed, showed no recurrences. They were classified as clinically cured, although roentgen examinations still showed a deformity of the duodenal cap. Recurrent cases were greatly improved. Complicated cases showed marked improvement in symptoms reported. One patient was discharged as clinically cured and has been followed for twenty months with no recurrence except a recent loss of appetite. Insulin either completely relieves or else causes a vast improvement in the symptoms. It is difficult to explain the persistence of positive x-ray signs in clinically cured patients who have had no recurrences of symptoms. One patient with gastric ulcer (malignant) reported relief from pain and increased appetite. Pyloric stenosis nullified the insulin beneficial effects. In the older group of complicated ulcers the patients were in many instances saved from major surgical procedures and restored to a useful existence. Insulin therefore offers a medical solution to the treatment of apparently hopeless cases that have been marked for surgery.

**Etiology and Treatment of Food Allergy.**—The Oelgoetzes and Wittekind advise that many chronic invalids complain of a host of gastro-intestinal symptoms but on examination show no abnormal physical signs. Some of these have true neuroses, but the greater number are sufferers from food allergy secondary to pancreatic hypofunction. Because a gastro-intestinal patient's reactions to foods are so confused by misinformation, biases, fads, prejudices, food likes and dislikes, and, in many cases, true food allergy, the history is more often misleading than informative. That part of the external pancreatic secretion produced when food is in the stomach and intestine (Boldyreff) combines with the food and serves a local digestive function, while that secreted when no food is in the stomach is absorbed into the blood stream to act as true buffers,

pressure on the labyrinth or on the brain stem is absent. In these cases, at least, it seems not unreasonable to assume that the vertigo may appear as a local symptom of the cerebral cortex due to direct lesion (stimulation) of the aforementioned cerebral areas, or due to pressure on these foci by tumors in neighboring regions. In general it seems that tumors close to the sylvian fissure induce vertigo more easily than do tumors more distant from this fissure.

**Chemotherapy of Experimental Typhoid Carrier State.**

—Coplans inoculated 104 immature rabbits with a single intravenous injection of a prepared strain of *Bacillus typhosus*. These rabbits proved without exception to be "carriers" of the specific organism, showing infection of the hepatic system up to the thirty-seventh week following inoculation. The organism was recovered from the bone marrow and from the feces up to the twenty-seventh week, from the former in 93.9 per cent and from the latter in 84 per cent. The urinary system was found to be infected up to the sixteenth week following inoculation, the urine proving positive in 79.1 per cent. The organism was recovered from the blood in 48.3 per cent of all animals examined up to the eighth week following inoculation, the latest positive result being on the forty-sixth day. Oral administration of methenamine-sodium acetate was found preferable to methenamine. Within fifteen days of the commencement of daily treatment the organisms disappeared entirely from the infected animals. When treatment was commenced ten days prior to infection, the organisms could not be found after seven days. Sodium acetate administered orally daily for 100 days rendered four of thirteen animals free from infection. Sodium mandelate administered for a similar period, while freeing the urinary system from organisms, failed to influence the infection of the gallbladder and bile, which remained positive in eight cases. Normal animals exposed to infection by contact with typhoid carriers for sixty-two days failed to show infection. The offspring of parents both of which were carriers were not found to be infected at birth.

**Intravenous Injections of Charcoal.**—Davis tested the effects of intravenous charcoal in healthy subjects, in patients with skin diseases and in 123 patients with fever of various origin. A 2 per cent suspension of charcoal injected intravenously into afebrile subjects often caused a rise of temperature, pulse and respiration, frequently associated with chills and rigors. To the febrile patients the charcoal was given in 2 per cent suspension in gum-saline solution, in saline solution alone or in distilled water, but the results did not vary with the vehicle, and wood charcoal did not differ in action from animal charcoal. In half the febrile cases the injections were followed by a rise in temperature, respiration and pulse within a few hours. Often the temperature reached was the highest since the beginning of the disease, and not infrequently it was the maximum for the whole illness. This rise was often followed

by an abrupt fall in temperature to normal, usually temporary; the rise and fall were over in eight hours. In the other half of the cases the temperature, respiration and pulse were not significantly altered. Subjective reactions were uncommon. For the trial of charcoal in febrile diseases, only those patients were selected who had been in the hospital at least twenty-four hours and who were not improving. The 123 patients received 24 injections of charcoal—usually from 4 to 5 cc. of a 2 per cent suspension. In most cases it was given in addition to ordinary therapy. Injections of gradually increasing doses were given at intervals of a day or longer for as long as the clinical condition and temperature, respiration and pulse did not show marked improvement. The results were compared with those obtained in similar control patients with the same disease who were in the hospital at the same time and whose treatment was the same except that they received no charcoal. No significant difference was found between these results; the death rates were approximately the same and so was the manner of recovery.

**Surgery of Urinary Tract in Childhood.**—Higgins states that the clinical manifestations of disorders of the urinary tract in childhood are general (pain, fever, presence of a tumor) disorders of micturition (frequency, urgency, pain and dribbling) and changes in the urine (odor, cloudiness, presence of blood and pus). Roentgen examination by means of plain roentgenograms, excretion pyelography and retrograde cystography and pyelography supplies valuable information. Preliminary preparation is necessary to get rid of intestinal gas. With the instruments now available it is possible to carry out cystoscopy and even ureteral catheterization in children from the age of approximately 18 months. Pyuria becomes a surgical problem when it persists in spite of treatment for a period longer than six to eight weeks or when it is recurrent in type. Developmental anomalies may be many and various. In the main their effect is to determine obstruction at some point or points in the urinary channel with resulting dilatation and stagnation of the normal flow of urine. Such stagnation predisposes to infection and, once infection has occurred, inflammatory swelling further aggravates the obstruction. A vicious circle is formed and recovery retarded. Apart from systemic disease, e. g., hemophilia, nephritis, injury or the transient smokiness which may mark the acute onset of urinary tract infections, hematuria in childhood may be the prominent symptom in meatal ulcer, calculus and tuberculosis. On rare occasions it may result from ulceration of the bladder, nevus growths, essential hematuria, congenital cystic kidneys and hydronephrosis. In obstinate cases of ulcer with a small meatus, meatotomy may be necessary. Removal of the calculus alone is not enough, the underlying cause, hydronephrosis, must be removed if possible to prevent recurrence. Provided the child's general health indicates that the tuberculosis in the urinary tract is the dominant lesion, and provided one kidney is chiefly involved, nephro-ureterectomy gives excellent results. In favorable cases of hydronephrosis, division of an abnormal artery and/or freeing of the ureter from adhesions have given gratifying results.

**Granules in Cells of Liver in Infections.**—Santee calls attention to the fact that in pathologic sections of the human liver and adrenal cortex fixed in formaldehyde or Zenker's fluid and stained with hematoxylin and eosin there appear in the cytoplasm oval, rod-shaped or club-shaped granules dark with hematoxylin. Their average size is about 1 by 3 microns, but they vary greatly. Their outlines are irregular. All the cells may be thickly dotted with them or there may be only three or four granules in an occasional cell. In the cells of the adrenal cortex they may be fewer than in the liver cells. They are stained red with pyronin. They have no special station in the lobule of the liver or in the adrenal cortex. They are often indiscriminately arranged within the cells. Since the granules occur very frequently and are quite distinct with the high, dry objective, they must have been seen by many observers. And yet little or no mention of them has been made in the literature.

**Antitryptic Activity of Egg White.**—Parsons prepared crude concentrates of an antitrypsin from a commercially fermented dried egg white which has been shown to be highly active in producing pellagra-like lesions in rats and other animals. These concentrates showed no corresponding increase in the capacity to produce the nutritional disorder but permitted the healing of the characteristic lesions when the diets incorporating them held a much higher concentration of antitrypsin than did the physiologically injurious diets carrying

the egg white or extracted residues. The pellagra-like syndrome due to egg white is not attributable to the antitryptic content of this substance.

**Retention of Vitamin B by Children.**—Knott has studied the utilization of vitamin B through biologic assay with rats of the amounts of vitamin B in the food and excreta of children receiving weighed diets. A total of twenty-three balance studies have been completed with eight children from 4 to 7 years of age. The children, who were selected from private homes and from a county juvenile home, were apparently in normal health. While being studied they were under constant supervision by nurses trained in metabolism technic. The utilization of vitamin B as affected by various levels of ingestion has been studied by comparing the retentions of the children during twenty-three metabolism periods. The dried food aliquots, dried feces and concentrated urine from the children were assayed for their vitamin B content according to standardized technic. The unit of vitamin B selected as being most suitable to the short period type of assay employed was the quantity of vitamin B causing 1 Gm. of gain. This unit is approximately equal to 2 Chase-Sherman units. Increasingly higher retentions were obtained with higher intakes for each level of ingestion studied. On the basis of the ingestions giving the highest retentions, the optimal requirement of vitamin B by young children is estimated to be 20 units per kilogram of body weight, or about 40 Chase-Sherman units per kilogram daily.

**Sodium Chloride in Treatment of Nocturnal Enuresis.**—Rosenson and Liswood treated twenty-eight cases of nocturnal enuresis by a dietetic regimen with sodium chloride: successful results were obtained in all but one, in which the child refused to cooperate. Before this regimen is instituted in any given case, any underlying physical or psychologic condition that might account for the bed wetting should be treated. If such attempts fail, the sodium chloride treatment offers an effective method. The child is given his regular diet during the day. Until noon he is allowed to take as much fluid as he desires; after that, fluids are somewhat limited until 4 p. m. At that time he is offered his last drink of water or milk until

operation: the disorder for which the operation is being performed, the state of the patient at the moment of operation and the surgical act itself. The best method of studying the humoral and tissue modifications following operations seems to be experimentation on absolutely well animals by close simulation of the human surgical technic. In this manner the authors studied the effect of starvation, anesthesia and the operation itself on some of the tissues. The starvation affects dogs only slightly and is characterized by some reduction in the quantity of water in the blood with a minimal reduction in the mineral elements. Diuresis is rapidly reduced and the urinary minerals excreted fall to a small quantity. The effects of anesthesia on the blood and urine are varied, depending on the type and duration of narcosis employed. In general there is a definite restriction in the amounts of urinary chlorides. The effects of the surgical act itself are more marked. The blood volume is reduced about 10 per cent in cases in which operative hemorrhage plays no part. The globulin-plasma ratio is increased because of loss of plasma. Globulin is generally also increased. Nonprotein nitrogen, urea and residual nitrogen are increased. The alkali reserve is slightly lowered and there is a definite drop in the sodium, potassium and calcium of the blood. In the urine there is a drop in total quantity and in mineral elements, especially chlorides. From the practical standpoint a study of the tissue syndrome of the postoperative period does not allow the formulation of adequate therapeutic measures for the changes observed. It is, however, necessary to restore the water balance of all those operated on in order to reestablish a nearly normal state. It seems wise also to give sodium, potassium, calcium and chlorides in satisfactory proportions by the subcutaneous method if necessary.

Progress in Study of Anaerobic Organisms Since the War. M. Weinberg.—p. 1913.

\*Dangers of Radioactive Substances Introduced into Body. S. Laborde.—p. 1915.

**Dangers of Radioactive Substances Introduced into Body.**—It is well known that radioactive substances introduced into the general circulation exert interesting therapeutic actions, but the accompanying dangers are not equally well known. The most common substances used, according to Laborde, are radon, mesothorium, radiothorium, thorium X, thoron and rarely the salts of radium. The knowledge of the fixation of radioactive elements and the electivity of their action on certain substances of the body serve to direct attention to the dangers which their presence may cause. Thus, their fixation at the level of the reticulo-endothelial tissues and the bony medulla readily explains their harmful action on all the blood-forming organs and the osseous tissue. The principal harmful effects, therefore, which these substances are likely to produce are osseous necroses, certain tumors of the bone, diseases of the blood-forming system and cutaneous accidents. Among the better known of the accidents of bone necrosis are those resulting from painting watches and clocks with radioactive substances. Similar disorders of the blood system have been reported from the professional use of radioactive substances and from therapeutic uses as well. From his review of this subject the author concludes that the therapeutic doses currently employed are frequently too close to toxic doses. There is no evidence that it is wise in therapeutics with such elements to exceed the dose of radioactive substances obtained from natural radioactive sources existing in some of the spas.

Urticarias Cured by Appendectomy. P. Chevallier and M. Colin.—p. 1942.

**Effects of Bleedings on Blood of Universal Donors.**—Much more attention has been paid to the recipient of a blood transfusion than to the donor. From the standpoint of the frequent donors, however, the results of large transfusions are important to both parties. Merklen and his collaborators examined twenty donors who had given quantities of blood varying between 2 and 15 liters. There were fourteen men and six women, ranging in age from 24 to 59 years. The number of red blood corpuscles was only slightly changed, there being a count of below 4,000,000. The hemoglobin was

found to be more variable, being between 60 and 70 per cent in four instances but lower in none. The white cells were normal except in two persons, in whom it was high in one and low in the other. In one patient there was one myelocyte. Nevertheless, ten of these donors showed more or less neutropenia, which was quite marked in three instances. This tendency to agranulocytosis constituted the single important factor uncovered by the examination. While of questionable significance, the authors believe that these facts point to the probability that the regeneration after transfusion is fastest in the erythrocytes, slightly less rapid in the hemoglobin and still slower in the white blood cells.

**Pathogenesis of Bronchiectasis.**—Löffler points out that opinions still differ as to whether bronchiectasis is a congenital or an acquired process. He emphasizes that in tuberculosis roentgenoscopy and in bronchiectasis auscultation is the more reliable diagnostic procedure. He discusses the condition of the sputum in the two disorders, and then bronchography. He presents the arguments in favor of the congenitality of bronchiectasis and groups them under four headings: localization, pathologic anatomy, concurrence of bronchiectasis with other deformities and the familial occurrence of bronchiectasis. The sites of predilection of bronchiectasis are the left lower lobe, the right upper lobe and the paracardial section in the right lower lobe. He emphasizes that not the lobes as such but rather the pertaining parts of the bronchial tree are responsible for the localization of bronchiectasis. The common characteristics of the three bronchial branches are their asymmetry and the fact that deformities are especially frequent in these branches. As to the pathologic anatomy of bronchiectasis, it is not permissible to consider as equivalent true dilatative changes of the bronchial wall, which are microscopically recognizable by the atrophy of the elastic elements, and suppurating, ulcerative changes in the parenchyma: bronchiectasis signifies dilatation; the suppurating destruction of the pulmonary parenchyma with or without involvement of the bronchial wall is an abscess and not a bronchiectasis. In discussing the concurrence of bronchiectasis with other deformities he cites reports from the literature and states that in the bronchiectasis material of his clinic (142 cases) he observed that bronchiectasis concurred with such conditions as status thymicolymphaticus, multiple cartilaginous exostoses, color blindness, heterochromia iridis, hereditary deaf-mutism, congenital cardiac defect, cystic kidneys and idiocy. The concurrence of bronchiectasis with chronic suppurations of the accessory nasal sinuses and particularly with situs viscerum inversus is another noteworthy factor. Regarding the familial occurrence of bronchiectasis the author says that he observed it in four pairs of cases, three times in siblings and once in cousins. He also cites cases of familial occurrence from the literature. He does not doubt the occurrence of acquired bronchiectasis, but he only wishes to emphasize that it is frequently congenital, even if the anamnesis seems to indicate infectious diseases or colds as the cause. In the individual instance it may be difficult to decide whether a case is congenital or acquired, but a survey of a large material justifies the assumption of congenitality.

**Leukocyte Formula in Gastroduodenal Ulcer, Before and After Gastric Resection.**—Ugelli states that association of lymphocytosis and eosinophilia, which is a common occur-

seven showed metastasis (56.1 per cent). Ten more cases had extended through the wall of the bladder without producing metastasis. The demonstration of early metastasis is difficult, but before any radical operation is undertaken roentgenography of at least some of the long bones, abdomen and chest should be proved negative. In all cases in which extensive resection or cystectomy is proposed the peritoneal cavity should be opened, by which procedure a satisfactory examination of the liver, of the glands along the great vessels and of the regional lymph glands can be carried out to exclude metastatic deposits. If metastatic deposits are demonstrable, radical methods are contraindicated and complete cystectomy should be reserved for those cases of infiltrating carcinoma in which other methods have failed, and only when the patient is in sufficiently good condition to withstand these rather formidable procedures.

**Jamaica Ginger Extract Paralysis.**—Weber bases his study on thirty-five cases of ex-service men from 28 to 54 years of age at the time of the onset of the paralysis, early in 1930, as the result of drinking adulterated Jamaica ginger. Twenty-two of the total number were personally examined by the author during June and July 1936; the remaining thirteen were examined by other physicians during the last two years. In his opinion the orthopedic and neurologic residuals, as seen from the material studied, are due solely to the original paralysis, even though four of the patients are known to have systemic syphilis and several others have continued to consume alcoholic beverages. The absence of cranial nerve involvement and the practical absence of mental manifestations preclude the diagnosis of either neurosyphilis or an alcoholic polyneuritis. The early (1930) prognosticated restoration of motor power in the paralyzed limbs has not materialized in a considerable number of cases. The residuals found were contractures, equinovarus, bilateral foot drop, wrist drop, steppage gait, atrophy of legs, atrophy of hands, exaggerated knee jerks and ankle, knee and patellar clonus. Four patients were unable to stand or walk. The greater disability of the legs, compared with the hands, is accounted for by the fact that the neurons of the legs are longer, requiring more time for their regeneration. The pathology involved appears to be of a combined lower and upper motor neuron degeneration: a neuronitis of the peripheral motor nerves and anterior horn cells, in addition to the lateral motor columns of the spinal cord itself. The prognosis for improvement, barring orthopedic and neurosurgical intervention, appears to be very grave. That the age

of the patient had any influence on the outcome of the disease was not observed. As nearly all the peripheral nerves (with the exception of some of the cranials) carry both motor and sensory fibers, it is curious that so little of sensation was impaired in even the most severe cases of the series. It is also curious that the toxin should strike the lower and upper motor neurons at the same time, phylogenically old and new parts of the motor system.

**Protein Deficiency.**—Jones concludes that acute or chronic protein deficiency has as its causes (1) an insufficient intake of protein, (2) failure of absorption and (3) an increased loss of protein from the body or, possibly, increased destruction or failure of regeneration of protein. Treatment consists in providing an adequate protein intake whenever possible, in the specific treatment of any other deficiencies that may at the same time interfere with the proper absorption of protein, in appropriate surgery with proper precautions in instances in which inadequate intake or insufficient absorption is due to a lesion of the gastro-intestinal tract, or in the more chronic cases in the use of transfusions and diuretics in order at least temporarily to alter plasma protein values. In all instances it is expedient to limit the intake of fluid and sodium chloride.

disease, roentgenokymography reveals atony or disturbances in the peristalsis. Roentgenokymography discloses atony of the ureters and of the renal pelvis in some cases in which simple pyelography may simulate normal conditions. Roentgenokymography is valuable also in the control of therapeutic methods in that it can be used for determining the degree of functional improvement that is effected by a therapeutic measure. The progressive recovery of the renal function after an operation for calculus can likewise be observed. Moreover, the roentgenokymogram of the urinary tract discloses whether the disorder is due to defects of the spinal cord (tumor or myelitis) or whether the bladder or a higher part (ureter or renal pelvis) is paralyzed.

\*Permanent Impairment of Heart in Children After Diphtheria. A. Beer.—p. 152.

**Impairment of Heart in Children After Diphtheria.**—In order to determine whether permanent cardiac impairment develops after diphtheria and what significance it has, Beer made a follow-up examination of children who had had diphtheria with cardiac complications during 1928-1935. Among forty he discovered seven who had noticeable cardiac disorders, in four of whom they were chiefly of a clinical and anamnestic nature with only slight electrocardiographic changes, while in the other three there existed only electrocardiographic changes. The author gained the impression that the cardiac impairments which appear in the course of diphtheria disappear largely in the course of the following years. He points out that Hecht expressed the optimistic opinion that the cardiac defects caused by diphtheria disappear generally in the course of months. In view of all this, the author concludes that the rôle which some authors have ascribed to diphtheria in the heart diseases of older persons is only a supposition and requires further investigation.

\*New Therapeutic Method of Essential Hypertension and of Related Conditions. H. Rutenbeck.—p. 1920.

**Lactic Acid in Gastric Contents.**—After demonstrating that Uffelmann's reaction is not a specific test for lactic acid, Never and Vincke point out that Denigès's color reaction is specific: they adapted it for the examination of the gastric contents. After several trials they found the following procedure the most suitable: First they determine the reaction of the gastric contents. If it is acid, it is used as such for the test; if it is not, it is acidified with a few drops of tenth normal hydrochloric acid. From 5 to 10 cc. of the gastric contents is boiled and then filtrated. The filtrate is rendered slightly alkaline by the addition of a 10 per cent solution of sodium carbonate. Then five drops of tenth normal solution of potassium permanganate is added for each cubic centimeter of filtrate. This mixture is brought once more to the boiling point until the forming manganese dioxide has completely precipitated. After filtration, 2 cc. of concentrated sulfuric acid is added to 0.2 cc. of filtrate. This is heated for two minutes in the boiling water bath and, after cooling down, from two to three drops of a 5 per cent alcoholic solution of guaiacol is added. The presence of lactic acid is indicated by a rose to carmine red coloration. In employing this test on patients with various disorders, the authors found that the lactic acid reaction was positive in patients with gastric carcinoma.

**New Therapy of Essential Hypertension.**—Rutenbeck describes craniocerebral electrophoresis as the new treatment for essential hypertension. He shows that craniocerebral elec-

trophoresis produces a reflex hyperemia of the brain. The substance he uses is a choline derivative and the maximum current strength is 1.5 milliamperes. With such low intensities, burns are avoided. The treatments, lasting about one hour each, are repeated every day or every second day. The author employed the method with good results in those cases of essential hypertension in which treatment was required on account of headaches, vertigo and so on, for he does not consider treatment necessary in all cases of hypertension.

"Prognostic Index" (Effect Index) in Treatment of Uterine Cancer. O. E. Nudolskaja.—p. 331.

**Essential Pregnancy Hypertension.**—Gaetgens points out that in the frequent concurrence of pregnancy nephropathy and increased blood pressure, the latter was generally regarded as merely of symptomatic significance. However, since the various forms of the edemonephrotic and eclamptic syndrome were separated and the monosymptomatic pregnancy toxoses were recognized, essential pregnancy hypertension was accepted as a manifestation of the toxic processes of pregnancy. The author describes a case history which reveals that in this case of pregnancy toxicosis there existed an elective disturbance of the neurovegetative apparatus. The family anamnesis of this patient revealed a hereditary instability of the neurovegetative system: it seems that in this case the hypertension was caused by a dysfunction of the neurovegetative and perhaps also of endocrine processes, which in turn was traceable partly to hereditary factors and partly to the pregnancy. It cannot be doubted that during pregnancy there occurs a form of hypertension that resembles essential hypertension and is accompanied neither by renal disturbances nor by angiospastic retinitis. It is possible, however, that the essential pregnancy hypertension gradually changes into the renal form with angiospastic retinitis and genuine contracted kidney. The author suggests that this interpretation might help to explain also the development of renal disease after eclampsia.

Acute Cutaneous Inflammations of the New-Born. E. Flusser.—p. 279.

**Modification of Anaphylactic Shock by Vitamin C.**—Clinical observations demonstrated to Lemke a greatly reduced incidence of serum disease in children who were constantly treated with vitamin C. In order to clarify the connections he resorted to animal experiments and found that the daily administration of cevitic acid to guinea-pigs sensitized with horse or sheep serum resulted in the survival of animals following the reinjection of a dose several times as large as the otherwise fatal one. This effect increased proportionately to the quantity of the administered vitamin C. Sensitization as well as shock could be inhibited by a single parenteral injection of cevitic acid thirty minutes before the sensitization or the reinjection, respectively. Tests that were made to exclude a nonspecific acid or reductive action disclosed that the observed effect is specific for cevitic acid.

**Meningeal Reaction in Erythema Nodosum.**—According to von Moritz, the etiology of erythema nodosum is not entirely cleared up, for, whereas some assume a special as yet unknown agent, others think that it is of tuberculous origin and represents a form of subcutaneous tuberculid and still others consider it an allergic or a parallergic skin reaction usually on the basis of a tuberculous allergy. The author thinks that, regard-

splitting whole serum proteins that are toxic and cannot be used as food to nontoxic split products that can be used. When the serum enzymes are in normal concentration, whole proteins cannot reach the cells in an unsplit state. As whole proteins are regular constituents of normal blood, it is the serum enzymes that prevent all of us from being food allergic all the time. In short, food allergy results from too much food, not too much for nutritional requirements but more food than can be hydrolyzed by the available pancreatic enzymes. Food allergy then is not a disease entity or a specific sensitization but a variation of a normal physiologic process. Pancreatic hypofunction may be secondary to a primary disease, syphilis or gallbladder disease for example, but more often no primary disease can be demonstrated. The tensions, stresses and strains of modern life with resultant nervous fatigue produce in the low threshold type of individual, first, overstimulation of the vagus (vagotonia) with oversecretion of the pancreas and, later, fatigue with hypofunction. Extreme fatigue often results in complete pancreatic achylia. Oversecretion of the pancreas produces mild hypoglycemia, while undersecretion permits serum proteins to reach the individual cells in an unsplit state not usable as food but producing the toxic effects known as allergy. Physiologic rest together with underfeeding to meet the lessened pancreatic secretion will quickly remedy many cases. If the reduced intake of food is sufficient for nutritional requirements, no other treatment is necessary. Sedatives help during critical periods. However, since the cause of the symptoms is not only the nervous system but the resulting pancreatic hypofunction, the most effective treatment is the administration of an extract of whole pancreas—preformed enzymes—to help out the inadequate gland. Fifteen grains (1 Gm.) of an active extract after each meal assures a sufficient concentration of serum enzymes to split all the food taken.

**Dilation of Benign Strictures of Esophagus.**—Hoag suggests a method for use in the dilation of esophageal strictures. It must be used with care and judgment, since injury or perforation of the inflamed and friable esophagus is always a real danger. The smallest Levine duodenal tube, 12 F., is used. Through it is threaded a piano wire (or a tonsil wire) the tip of which has been looped and inserted into a hole burned into the blunt end of the tube. The wire and the tube together are then grasped with a hemostat to prevent slipping. The tube with its stylet is introduced through the mouth into the esophagus. As the tube is passed down the esophagus the stricture is located. If it does not pass the stricture by gentle pressure, 4 or 5 cc. of liquid petrolatum is injected into the tube with a syringe so that it will emerge at the point of the lesion. Again the tube is turned slowly, pressure with the tip being exerted in various directions. Frequently the tube will slide through the stricture into the stomach, allowing the introduction of food and maintenance of a passageway for future treatment. The use of a series of Levine tubes of increasing size acts the same way in the esophagus as a rubber tube in any other sinus and produces a gradual and more permanent dilatation of these strictures as well as providing a means of feeding the patient during the process. It has proved to be a successful method of treating these strictures.

- \*Milk Allergy in Elementary School Children: Preliminary Report. D. A. Williams.—p. 1081.

**Milk Allergy in School Children.**—Williams inquired into the family histories of 150 elementary school children who had refused milk at school. Of these, 124 appeared to be allergic to milk. They all had symptoms after milk, or a very definite dislike of it, and all except five gave a personal or family history of allergy. Twelve disliked the school milk only because of its taste (it was pasteurized), but it is significant that five of them came from allergic stock. Fifteen children refused the school milk for reasons unconnected with health. It did not disagree with them and apparently they were normal children; only two had allergic histories. Forty normal children taking milk readily without ill effects were examined as a control; only four gave a personal or family history of allergy. While the popular movement to encourage the widespread consumption of milk has much to commend it, the fact that not every one can take it with impunity should be remembered. The refusal or disinclination of many children to take milk at school should be given due consideration. Their attitude is probably protective in nature to prevent them from suffering allergic reactions and possibly also to give them time to develop a gradual immunity to milk. Desensitization to milk not infrequently occurs as a result of its omission from the diet over a lengthened period, and the degree of tolerance often varies with the interval. Thus milk should not be forced on these children but rather withheld.

killed and the histologic studies revealed that the allergy experiment by means of eclampsia serum produces in the liver and kidneys of pregnant rabbits anatomic changes indicating a hyperergic reaction. The morphologic pictures greatly resemble those of eclampsia.

**Delivery of Shoulders in Large Children.**—Tüscher describes a case in which he encountered difficulties in the delivery of the shoulders. He says that, if the abnormal presentation of the breadth of the shoulders at the pelvic inlet is the cause of the difficulty, the fetal head, following its external rotation backward, should be directed downward toward the perineum, for by this maneuver a correct presentation of the shoulders can often be effected. If in case of correct presentation the difficulty lies only in the excessive size of the shoulders, it is again advisable first to make an attempt to deliver the shoulders by bringing the head downward. This mechanism is further promoted by pressure on the fundus and if necessary by slight traction on the fetal body in the direction toward the perineum. If these attempts at extraction should fail to succeed and the downward pulling of an arm should no longer prove feasible, the author recommends that the extraction efforts on the head should not be further continued, but a rotation of the shoulders should be resorted to by first loosening the shoulder girdle slightly and then making screw-like movements.

### Problemy Tuberkuleza, Moscow

Tuberculosis of Bronchial Lymph Nodes in Children. E. E. Granat.—p. 1517.

**Treatment of Tuberculous Peritonitis.**—According to Zhmakin, the course of tuberculous peritonitis in children differs considerably from that in adults. In children tuberculous peritonitis more frequently runs a mild latent course. A clinical cure may be obtained in a few months. Tuberculous peritonitis in adults pursues a more chronic course. Protracted, recurring forms, lasting ten and more years are frequently observed. Absorption of the exudate and of solid tuberculous nodes is slow and not infrequently remains arrested at some stage. Metastatic processes are observed in adults much more frequently than in children. Laparotomy performed during the acute stage of the disease is likely to give rise to metastatic phenomena and activation of the process. Laparotomy is seldom indicated in tuberculous peritonitis of children. It is of value in adults when latency of the process is unduly protracted. The Spa-Sanatorium treatment of tuberculous peritonitis in Eupatoria (Crimea) gives excellent results in both children and adults, the children, as a rule, making a more complete and quicker recovery. The spa treatment is contraindicated in the stenosing forms of tuberculous peritonitis as well as in cases with marked debility, high fever and an active process in the lungs.

**Rational Therapy of Tuberculosis.**—According to Golyanitskiy, most authors believe that in tuberculous infection allergy is not definitely related to immunity. Allergy here cannot be regarded as an immunity reaction. The fate of a tuberculous patient depends on the natural defense mechanisms. Immunity does not play the determining part in the cure. Local regenerative processes of the connective tissue play an important part in the natural immunity. The tubercle itself represents a typical regenerative process. In the presence of normal regenerative power of the organism the tubercle is converted into a scar and the infection is thus terminated. When the regenerative power is insufficient or the virulence too great, the tuberculous lesions develop into an exudative or caseating form. The author concludes that treatment of tuberculosis depends on the restoration of the normal regenerative processes. This in turn depends on normal nutrition of the affected tissues and on their normal oxidation. In his treatment of bone and joint tuberculosis the author reduces the

foregoing to restoring (1) the blood to normal, (2) the acid-base balance, (3) the normal mineral metabolism and (4) the normal vitamin balance. The first condition is best accomplished by transfusion of small doses (from 100 to 150 cc.) of freshly conserved blood, by transfusion of small amounts (from 15 to 20 cc.) of incompatible blood or by autohemotherapy (5 cc.). An effective therapy of altered acid-base balance consists in the increase of gaseous exchange. This is best met by life outdoors. Alterations in the mineral balance are determined by roentgenologic examination of the bones and by determinations of the blood calcium. Decalcification is treated by intravenous introduction of from 5 to 10 cc. of calcium chloride every other day and drinking adequate amounts of milk. The general hypovitaminosis, as reflected in the deficiency of vitamin C, is made up by the feeding of carotene, carrots, yeast, cod liver oil and so on. On this regimen, in conjunction with the general adequate nutrition and local orthopedic procedures, positive results are obtained in a much shorter time.

### Acta Tuberculosea Scandinavica, Copenhagen

10: 321-376 (No. 4) 1936

From Childhood Infection to Adult Type of Pulmonary Tuberculosis. A. Wallgren.—p. 321.

Attempts to Treat Tuberculous Cutaneous Disorders with Lecithin Tuberculin. K. Hedén.—p. 340.

Endogen Factors in Occurrence of Erythema Nodosum. A. Roosvall.—p. 351.

\*Pulmonary Tuberculosis Caused by Bovine Type of Tubercle Bacillus: Thirty-Three Cases. P. Mourier.—p. 356.

\*Glutathionemia in Tuberculosis of Bones. M. M. Altschuler.—p. 370.

**Pulmonary Tuberculosis Caused by Bovine Bacillus.**—Mourier reports about thirty-three cases of pulmonary tuberculosis that were caused by the bovine type of tubercle bacillus, the type identification having been made in the state serum institute. Of the thirty-three patients twenty-five had been in direct contact with cattle, and of the other eight only three apparently had had no connection with farming. Thirty of the patients admitted that they had taken raw milk, but three could not state that with certainty. In ten of the patients the anamnesis revealed the familial occurrence of tuberculosis; however, in most of these cases there had been no contact with the diseased members of the family. In one case there was considerable evidence that the bovine infection had been spread from man to man in the hospital. Transmission of the infection from cattle to man seemed probable in twenty-nine of the patients. The author gained the impression that the clinical aspects, the course and the prognosis of the pulmonary tuberculosis of bovine origin do not differ from those caused by the human type of tubercle bacillus.

**Glutathionemia in Tuberculosis of Bones.**—Altschuler, after reviewing the literature on glutathione, reports his own investigations on the glutathione content of the blood of children with tuberculosis of the bones and joints. He found that the total amount of glutathione increases in the closed and open forms of tuberculosis of the bones and joints. The more severe the process, the higher are the glutathione values in the blood. In the closed form of tuberculosis of the bones and joints, the reduced form of glutathione shows a decrease in the venous blood if the process becomes more severe. The quantity of oxidized glutathione increases in these cases absolutely as well as in relation to the reduced form. In open tuberculosis of the bones and joints the increase of the oxidized glutathione in the venous blood is less severe. The glutathione coefficient is increased in tuberculosis of the bones and joints and, as the process exacerbates, the increase becomes even more pronounced. The author concludes that, besides the clinical picture, the fluctuations in the glutathione content of the blood permit an estimation of the course of the tuberculous process in the bones and joints.

### CORRECTION

**Cardiac Asthma.**—In the abstract of Weinberger's article in THE JOURNAL, January 30, page 433, the dosage of morphine and atropine to be injected should be from 1 to 2 cc. of morphine, to which from 0.5 to 1 mg. of atropine has been added.

who take care of tuberculous patients will in due time become infected. The incidence of infection in student nurses at the end of their senior year varies in hospitals that have a tuberculosis service or an affiliation from at least 56 to almost 100 per cent. Only a small percentage of those who are infected are ever harmed in the least by their infection. According to laboratory experimentation, a mild infection increases the natural resistance to exogenous reinfection when the reinfection occurs not sooner than four to six weeks after the first infection. A tuberculin-positive nurse is less likely to develop serious and fatal tuberculosis as a result of caring for tuberculous patients than is the tuberculin-negative nurse. Eighteen, or 16.5 per cent, of the supervising nurses gave x-ray evidence of the adult type of tuberculosis on the initial roentgenogram and another seven, or 8.3 per cent, subsequently developed active adult tuberculosis. Thirty-six, or 8.9 per cent, of the general duty nurses gave x-ray evidence of the adult type of tuberculosis on the initial roentgenogram and another twenty-five, or 6.2 per cent, subsequently developed x-ray evidence of the adult type of tuberculosis. Sixty-eight, or 6.4 per cent, of the student nurses had x-ray evidence of the adult type of tuberculosis on the initial roentgenogram, and subsequently an additional fifty-three, or 4.9 per cent, developed x-ray evidence of the adult type of tuberculosis. In order to minimize the hazard to nurses, the patient should be taught to cover his mouth with a fresh paper napkin every time he coughs or sneezes and to expectorate into a paper cup that can be burned. Scrub basins should be provided so that the nurse may wash her hands thoroughly at frequent intervals. Each nurse should have a clean gown daily and should be roentgenographed at the beginning of employment or when she enters the hospital as a student and at regular intervals thereafter. Working conditions should be comparable to those in industry, in which the exposure to disease and strain is not as great as it is in the nursing field. A course of instruction should be given all nurses, including lectures and special conferences, so that she may be informed of the nature of the disease and how to protect herself against it, and only students who are tuberculin positive should be admitted to the nurses' training schools or the employment of nurses in a sanatorium limited to those who are tuberculin positive.

Contribution to Knowledge of Marginal Corneal Ulcer: Report of Five Cases. P. S. Soudakoff.—p. 1393.

**Swimming Pool Conjunctivitis.**—Since June 1934 Ling has observed fifty-three typical cases of superficial punctate keratitis conforming to the description given by Ernst Fuchs. For twelve years previously neither the author nor his colleagues encountered any condition of this kind with the exception of one case, which was questionable. The cases under discussion appeared in the eye clinic of the Peiping Union Medical College in rather quick succession within a comparatively short period and many of them were associated with so-called swimming pool conjunctivitis. The incidence was most marked in the latter part of 1934. A certain relationship seemed to exist between superficial punctate keratitis and swimming pool conjunctivitis, although the former could occur independently of the latter. It is possible that the two conditions had one and the same etiology. The simultaneous occurrence of these two conditions does not seem to have been mentioned in the literature. As swimming pool conjunctivitis is probably of genito-urinary origin, it can naturally occur under any circumstances and may be transmitted from one person to another at any time. Accordingly some authors have suggested the name "adult inclusion conjunctivitis" or "inclusion blennorrhea of the adult" instead of swimming pool conjunctivitis, which may be misleading.

### Bulletin de l'Académie de Médecine, Paris

116: 424-490 (Dec. 1) 1936

\*Endocrine Origin of Prostatic Hypertrophy. B. Cunéo.—p. 434.

Acute Poliomyelitis in Paris During Last Three Years. Tannon and A. Besson.—p. 446.

**Endocrine Origin of Prostatic Hypertrophy.**—The object of Cunéo's report is to show that the type of hypertrophy usually called prostatic adenoma is of endocrine origin. From a structural standpoint the adenoma has the same constitution as the prostate itself. It is formed essentially by a group of nodules, of which the center is a glandular cavity comparable to the prostatic glandules and the periphery a fibromuscular capsule. These facts led to the opinion that the prostatic adenoma develops not from the prostate properly speaking but from the elements placed in its center near the ureter and above the origin of the verumontanum. The usual age of appearance is between 50 and 60 years and coincides with the period of decline of genital activity. Clinical observations reported by Cunéo, although small in number, led him to the conclusion that treatment with estrogen gives excellent results from the functional standpoint. In patients observed for more than three years, the impression was gained that because of the treatment, separated by periods of rest, the disorder remained stationary if it did not even regress. He believes that the development of the adenoma is the consequence of weakening of the secretion of estrogen. The latter may be combated by administration of estrogen either orally or subcutaneously. The use of estrogen is also recommended especially from a preventive standpoint.

### Bulletin Médical, Paris

50: 815-832 (Dec. 5) 1936

\*Indications for Hepatic Opothrapy in Asthma. Girbal.—p. 817.

**Liver Therapy in Asthma.**—Asthma is a syndrome of toxic infectious origin superimposed on a predisposed ground affected by endocrine disequilibrium. Therefore, according to Girbal, asthma does not exist without hepatic insufficiency, and without hepatic treatment permanent cure of asthma is impossible. He has observed numerous cases confirming this opinion but cites three characteristic ones in the present article. He believes that in all asthmatic patients, if systematic search is made, signs of hepatic insufficiency can be found. Thus in an examination of the urine of 100 asthmatic patients he found traces of sugar in fifty-eight, excess urobilin in forty-eight, traces of albumin in fifty-five and biliary salts in forty-one. Similarly, clinical examination frequently reveals dyspepsia, migraine or other symptoms indicative of functional hepatic insufficiency. Furthermore, the systematic treatment of asthma with oral or hypodermic liver extracts, as well as the specific bacterial product indicated, leads to favorable results. Chologogues, because of their action on congestion in the liver, are also indicated.

Changes of Cardiovascular System in Actors. A. M. Vydrine.—p. 1895.

**Rare Form of Insomnia.**—Lacassie investigated the factors involved in postoperative insomnia and found that the most important are vomiting and the results of morphine injections. Morphine injected for pain unquestionably assists in the development of nausea and vomiting. Furthermore, experience has shown that a number of injections of morphine are followed by insomnia, in spite of the suppression of symptoms that necessitate them. The author believes that postoperative insomnia can be classified into several types; namely, early insomnia, which develops in the hospital and is more postoperative than postanesthetic and has probably a complicated mechanism, and late insomnia, the mechanism of which appears to be more postanesthetic than postoperative. A partial late insomnia also apparently exists, characterized by more or less poor sleeping but which is usually readily amenable to hypnotics.

**Postoperative Humoral and Tissue Syndrome.**—According to Bottin and Conradt, three factors must be considered in the study of the tissue changes resulting from surgical

machine. The nonsoluble material is removed by centrifugation and the supernatant fluid is saved. The residue is washed once with water; this supernatant fluid is added to the first. The aqueous extract is washed with ether and is then tested for its content of gonadotropic substance by injection into infantile mice. I have also tried 0.02 per cent sodium hydroxide or 1 per cent ammonia water for the extraction instead of water, but the results were no better. Assays are stated in terms of 1 Gm. of fresh tissue.

Some examples may be cited from the literature of cases in which urinary hormone assays prevented serious errors: Dietrich<sup>7</sup> describes the case of a young woman in whom a histologic diagnosis of chorionepithelioma had been made. As the pregnancy test was negative eight days later and remained negative

on repetition at intervals of four weeks, operation was postponed. The patient remained healthy. The hormonal urine assay demonstrated the incorrectness of the histologic examination and the young woman was saved from a mutilating extirpation of the uterus. In another woman, aged 25, reported by Fahlbusch,<sup>8</sup> histologic examination performed by Robert Meyer, an expert on chorionepithelioma, suggested malignant degeneracy of the villi. There was a retained placental fragment with destructive epithelial proliferation of such a nature as to render possible invasion of the uterine wall. The hormonal urine reaction was negative. As the patient wanted a child, intervention was delayed especially as further urine tests were also negative. The patient remained healthy. In contrast, Balkow<sup>9</sup> reported a case in which histologic examination of the curettage material was inconclusive, while assay of diluted urine gave a positive pregnancy test. On extirpation of the uterus a well encapsulated, reddish brown tumor somewhat larger than a plum was found in the cavum. This tumor histologically was indisputably a malignant chorionepithelioma. Kimbrough<sup>10</sup> made a diagnosis of chorionepithelioma five weeks after discharge of a mole based on increasing gonadotropic potency of the urine and cystic enlargement of the ovaries despite the absence of uterine hemorrhage.

Following are descriptions of three cases of malignant chorionepithelioma which I have examined in the past two years. In addition to the urine the tumor tissue also was examined; in one case the spinal fluid and in another the pituitary gland was investigated:

CASE 1.—A woman, aged 38, had not been pregnant for the last ten years. In the beginning of 1935, menstruation failed to occur for two weeks; then a slight hemorrhage occurred. Curettage, performed in Europe, apparently did not show anything suggestive. In June the patient had a severe hemorrhage. Curettage at that time indicated an indisputable malignant chorionepithelioma (Dr. Casper). Urine assay, performed by me, showed an excessively high content of gonadotropic substance (1,000,000 mouse units of follicle-stimulating factor and

55,000 mouse units of luteinizing factor per liter of morning urine). So high a hormone excretion indicates with certainty the presence of a chorionepithelioma. July 1, 1935, total extirpation of the uterus and adnexa was performed by Dr. Danziger of Tel-Aviv, who kindly placed at my disposal the surgical specimen.

The excretion of gonadotropic substance declined strongly after operation; 500,000 mouse units of follicle-stimulating factor and only 500 mouse units of luteinizing principle per liter were now found in the urine. The patient, who felt very well, was treated postoperatively with irradiation (Professor Halberstädter). She received 1,480 mg. hours of radium intravaginally from July 21 to 29, 1935, and in addition up to August 7, high voltage roentgen irradiation to a total of 3,550 roentgens. Five days after termination of the irradiation the urine was assayed once more and showed a further decrease in excretion of follicle-stimulating factor (only 555 mouse units per liter). In contrast, however, the content of luteinizing principle had decreased scarcely at all (416 mouse units per liter). Thus the pregnancy test remained positive even after irradiation.

In the following weeks the patient felt well and gained weight; she believed herself cured. The blood picture was normal. In contrast to the clinical condition, urine assays showed an increased excretion of gonadotropic hormone. August 23, two weeks after the last irradiation, the content of follicle-stimulating substance had increased from 555 mouse units to 3,333 mouse units and the content of luteinizing factor from 416 mouse units to 555 mouse units per liter of morning urine. These observations indicated with certainty that metastasis must have occurred somewhere in the body. Made watchful by the result of the urine assay, we searched for a metastasis. Four weeks later a lesion was found in the left lung by x-ray examination, at the level of the third rib. High voltage roentgen therapy was administered over the lung from October 4 to 10 and from November 7 to 24. Gynecologic examination showed nothing pathologic in the pelvis. Clinically the patient continued to feel well and was fully able to work. The gonadotropic potency of the urine quickly increased (table 1).

In December the patient began to lose slightly in weight and was paler. A metastasis (diameter 1 cm.) was now visible roentgenologically in the base of the right lung. Furthermore, in the left parametrium a small hard nodule was felt, growing rapidly; it reached the size of a fist within three weeks and caused trouble by pressure on the bladder. Hemoptysis occurred and the patient complained of head pressure, headache and dizziness. These symptoms increased in intensity, indicating

TABLE 2.—Tissue Assays in Case 1

Chorionepithelioma (uterine tumor).....	1,500	800
Uterine mucosa.....	1,000	100
Ovary.....	150	0

cerebral metastases. In the middle of January the patient became somnolent. February 17 death occurred with symptoms of cerebral tumor. Autopsy was not permitted.

Tissue Assay.—The surgical preparation showed a spongy tumor the size of a plum, well delimited in the right corner of the fundus. The tumor infiltrated the musculature without reaching the serosa. The following tissues were assayed: (1) the tumor tissue itself, (2) the mucosa of the left uterine wall at a spot distant from the tumor, and (3) the ovaries. The tissues were extracted and the extracts assayed (table 2).

CASE 2.—A woman, age 36, born in Persia, had had five pregnancies, the last five years before. In September 1934 an abortion occurred. There was no suspicion of a mole at that time. Beginning in January 1935 the patient had irregular, occasionally severe hemorrhages. At the end of November 1935 she was admitted to the hospital in a bad general condition. (This case was referred to me by Dr. Sadovsky of Jerusalem.)

Gynecologic examination indicated the presence of a chorionepithelioma. A partly necrotic tumor the size of a plum was found in the anterior vaginal wall; it was very soft and bled

rence in patients suffering from gastroduodenal ulcer, is not a characteristic blood picture of ulcer but an indication of vagotonic constitution of the patient. Vagotomy determines a gastric angiospasm which predisposes to the development of ulcer. The leukocyte formula can be altered in patients suffering from gastroduodenal ulcer complicated by infection or hemorrhage. The last two mentioned complications may determine the production of neutrophilia, which can be controlled by repressing the complicating infection or the causal factor. The author made determinations of the leukocyte formula in seventy-three patients suffering from gastroduodenal ulcer before and late after gastric resection. He found association of lymphocytosis and eosinophilia in 40 per cent of the cases before and late after the operation. Cases complicated by infection or hemorrhage showed neutrophilia, which disappeared after gastric resection.

**Parallel Blood Changes After Splenectomy.**—Deleonardi and Paolazzi studied the behavior of the peripheral and medullary blood immediately and late after splenectomy in dogs. They found that immediately after splenectomy the total number of globules in the peripheral blood, especially those of minimal resistance and the reticulocytes, increase. Erythrocytes and reticulocytes diminish in the medullary blood. Peripheral polyglobulia has a medullary and splenic origin. The liberation of medullary cells to the blood is controlled by splenic nervous reflexes and splenic substances, the lack of which results in lowering of the "medullary threshold" with consequent passage of immature cells (reticulocytes) through the myelohematic barrier. The passage of splenic cells, especially those of minimal resistance, takes place during contraction of the spleen by the maneuvers that precede ligation of the splenic vessels in splenectomy. Late after splenectomy the resistance of the blood cells, in both the peripheral and the medullary blood, increases. In the peripheral blood, cells of maximal resistance appear which do not exist in the blood of normal dogs. In the peripheral and medullary blood the number of reticulocytes and cells of maximal resistance increases and that of erythrocytes diminishes. The authors say that the increased osmotic resistance of erythrocytes that follows splenectomy is due to the lack of hemolysis because of the absence of the spleen. The increase of reticulocytes and the appearance of hyperresistant cells in the circulation is due to the lowering of the "medullary threshold" which results from splenectomy.

**Kaposi Sarcoma.**—Greco reports a case of familial Kaposi sarcoma. In the course of the last twenty years, two brothers died from the disease and at present the third brother and a nephew are suffering from it. There have been no cases of the disease in the women of the family, although they came in contact with the patients as much as the men did. The disease in all cases followed a protracted evolution. The author was

able to make an etiologic study from the infectious, parasitic and microbiologic aspects in two of the patients. The disease began with edema of the legs and pain of the extremities and evolved with late appearance of cutaneous pigmented spots and nodules, which were hard at first and then softened. The liquid obtained by puncture of soft nodules coagulated in a test tube on the first day, but the coagulum was subjected to partial lysis by the third day. On microscopic slides it suffered lysis in twenty-four hours. Mycotic cells were identified in the liquid both by direct observation of the liquid placed in a sodium hydroxide solution and by microscopic examination of fresh and stained preparations of the liquid. Mycotic cells were not found in histologic preparations made with tissues taken for a biopsy of the nodules. Attempts to culture the fungus and to transmit the disease to rabbits failed. According to the author, the fungus found in his cases is the causal agent of the disease. The nature of Kaposi sarcoma as a mycosis explains the slow evolution of the disease. Softening of the nodules is due to mycotic ferments. The author concludes that Kaposi sarcoma is a mycosis and at the same time an infectocontagious disease which can be transmitted by direct and indirect contagion like other common infections. The incubation period of the disease varies from one to ten years. The disease attacks adults and old persons and more frequently men than women. The ages of the patients reported by the author were 28, 32, 58 and 59 years. The fungus has not been identified but probably belongs to the genus *Aspergillus* or is a cryptococcus.

**Cardiac Movements in Case of Elevation of Diaphragm.**—Böhme and Wawersig investigated whether in addition to the already known positional changes of the heart in case of elevation of the diaphragm, which may produce the so-called gastrocardiac syndrome, there exist still other changes in the movement of the heart as a whole or of some of its parts. They found that in all cases of chiefly left-sided elevation of the diaphragm the following can be demonstrated in addition to the already known topographic changes: 1. Elevated diaphragm in case of relatively slack diaphragm; that is, gastric eventration and diaphragmatic hernia produce a heart action resembling the tachycardia of pneumothorax. 2. A rigidly stretched left side of the diaphragm above a greatly distended stomach or colon is capable of causing from below a considerable compression of the cardiac muscle when it is relaxed during the diastole. 3. A diaphragm that is displaced in such a manner may elevate the heart during every diastole to such an extent that during every systole the heart has to press the diaphragm downward while it rotates around its sagittal axis. The conditions mentioned under points 2 and 3 may be absent, but their existence is a measure of the displacement of the heart by the diaphragm. Both of the latter phenomena represent a reversal of those conditions which correspond to the normal apical impulse according to the theory of Ludwig. Such conditions and particularly the abnormal modes of cardiac movement caused thereby, if they gradually increase in severity, will impose excessive work on the heart and will cause considerable subjective symptoms in affected persons.

**Roentgenokymographic Studies on Renal Pelvis and Ureters.**—Maintz and Wüllenweber show that Stumpff's roentgenokymograph makes possible the exact study of the normal and pathologic movements of the renal pelvis and ureters. It reveals the number and amplitude of the contractions and regularity or irregularity of the ureteral waves. In case of

urine. Of course, at the same time the content of luteinizing factor must be determined; usually this is correspondingly increased. But this is not always the fact, as illustrated by case 1.

While the presence of a definite amount of luteinizing factor (at least 416 mouse units per liter of urine) affirms the diagnosis of pregnancy, such exact numerical values cannot be obtained from a pathologic placenta (mole, ...).

(a) If a woman is pregnant and if there is a suspicion of the presence of hydatidiform mole, pregnancy toxicosis must first be excluded. If there is no toxicosis and if the content of luteinizing factor amounts to more than 200,000 mouse units per liter of morning urine, it is likely that a hydatidiform mole<sup>14</sup> is present. One assay is insufficient, however. The more the content of gonadotropic substance increases in the course of observation the more certain will diagnosis become. The spinal fluid should also be examined. If the pregnancy test (reaction II or III) can be obtained with undiluted or diluted spinal fluid, this may be important support for the diagnosis. According to my present experience I would make the diagnosis of hydatidiform mole if at least 200,000 mouse units of luteinizing factor is present in a liter of urine on repeated assays, and if in addition at least 416 mouse units per liter is present in the spinal fluid.

(b) If a patient has discharged a hydatidiform mole and thereafter the pregnancy test has become negative, to become positive again in the course of several weeks, the presence of at least 416 mouse units of luteinizing factor per liter of urine, in case a new pregnancy can be excluded, will in itself indicate a diagnosis of chorionepithelioma. A similar amount in spinal fluid confirms the diagnosis. The hormonal diagnosis of chorionepithelioma is not difficult, for the reason that the content of luteinizing substance in the urine is usually far more than 416 mouse units per liter (up to 1,000,000 mouse units per liter).

In case 3 the amount of gonadotropic substance in the urine was relatively small, being only 100,000 mouse units each of follicle-stimulating and luteinizing factor per liter. These relatively small values may have been due to the fact that the patient was in a bad general condition. The urine was examined some days before death. As I reported in 1930,<sup>15</sup> women suffering from carcinoma frequently discharge follicle-stimulating factor in the urine. When the general condition deteriorates acutely, this principle frequently disappears from the urine. This has been confirmed by Borst, Döderlein and Gostimirović.<sup>16</sup>

For the diagnosis of chorionepithelioma the demonstration of gonadotropic substance in urine and spinal fluid is more important than its presence in the blood. In case 2 the blood contained 500,000 mouse units of follicle-stimulating factor per liter; on the same day, however, the urine contained double this amount of hormone. The content of luteinizing factor in the urine was four times as high as in the blood; 1,000,000 mouse units per liter of urine, 250,000 mouse units per liter of blood. However, I have not yet seen such high values for the blood except in chorionepithelioma.

It is necessary to observe excretion of gonadotropic substance continuously in chorionepithelioma; this is more informative of the progress of the disease than the clinical signs. If an essential decrease in production occurs following therapy (operation, x-ray) this is prognostically favorable. As long as the pregnancy test in urine remains negative, namely less than 416 mouse units of luteinizing substance per liter of urine, prognosis is favorable. In case the pregnancy test, in spite of treatment, remains continuously positive, the prognosis is bad; in case the hormone content increases in spite of therapeutic measures, the prognosis is distinctly unfavorable, as this is an indication of metastasis.

Qualitative and quantitative tissue assay for gonadotropic substance has scarcely been employed for the diagnosis of chorionepithelioma. Considering the enormous inundation of the body with this hormone, it seems likely that it would be found in relatively high concentration not only in the tumor itself but also in other tissues of the body. Nevertheless, the difference is considerable, as I found in case 1; the tumor contained a far higher content of gonadotropic principle than either the uterine mucosa or the ovary. In my experience such a high content of hormone occurs only in chorionepithelioma and not in other malignant tumors. In the latter the luteinizing factor is not found at all,<sup>17</sup> or very rarely, and the follicle-stimulating factor only in relatively small amounts (1 mouse unit per gram of fresh tissue). The presence of 800 mouse units of luteinizing factor per gram of fresh tissue establishes the diagnosis of chorionepithelioma. (The tissue must be fresh and should not show signs of necrosis.) In the normal placenta in the seventh week of pregnancy I have found 143 mouse units of follicle-stimulating and luteinizing factors in 1 Gm. of fresh tissue by implantation. Still larger amounts of hormone can probably be demonstrated by the extraction method. Assays of between 100 and 300 mouse units per gram can be obtained with retained placental fragments. In metastases, however, the presence of 100 mouse units of luteinizing factor per gram is sufficient to establish the diagnosis of chorionepithelioma. Occasionally there are no definite signs of chorionepithelioma in the uterus at autopsy; if in such a case one finds a value of 100 mouse units per gram in some metastasis, e. g., in a cerebral or liver tumor, the diagnosis of chorionepithelioma is established.

Also in chorionepithelioma of men, assay for gonadotropic substance is of importance, particularly in mixed testicular tumors. In a lecture at the Viennese Biologic Society (April 15, 1929) I<sup>1</sup> pointed out, with reference to the strongly increased excretion of gonadotropic principle in the chorionepithelioma of women: "It will be very interesting to examine the urine of men suffering from a chorionepithelioma, in order to determine the biologic identity of these epitheliomas." Some weeks later (May 1929) I was in a position to examine a case<sup>18</sup> of malignant testicular tumor; a greatly increased excretion of the hormone was detected (both follicle-stimulating and luteinizing factors). This was a mixed tumor with chorionepitheliomatous elements. The biologic identity of these epitheliomas in men and women is now established. By assay of the tumor material (implantation or, still better, extraction) evidence may be derived as to the nature of the tumor. Thus I did not find any gonadotropic substance

14. It must be mentioned that in the literature there are several reported cases of hydatidiform mole without increased excretion of gonadotropic substances. These cases, although very rare, indicate that a normal content of gonadotropic substance in pregnancy urine does not absolutely rule out the presence of a hydatidiform mole.

less of whether the one or the other opinion is accepted, it is certain that erythema nodosum is not a local skin disorder but rather a partial manifestation of a general reaction of the organism. The general symptoms such as fever, headaches, loss of appetite and severe depression, which accompany the erythema nodules, corroborate this. The reaction capacity of the skin and of the entire organism is changed. The blood sedimentation is accelerated; there is leukocytosis and a slight deviation to the left. Roentgenoscopy reveals in some cases perihilar infiltration. The observation of meningeal symptoms in a case of localized erythema nodosum induced the author to give especial attention to the meningeal symptoms and to resort to the chemical examination of the spinal fluid. He studied the spinal fluid in ten cases. A tabular report of the results indicates that the pressure of the fluid was increased, probably as the result of an increase in the quantity of the fluid. The author thinks that in the examined cases the meningitis reaction as well as the erythema nodules and the perihilar infiltrations were all manifestations of an allergic reaction. Intracutaneous tests with increasing doses of tuberculin in three of five tuberculous children resulted in meningeal symptoms, which disappeared again after a few days or a week. In these cases too the examination of the cerebrospinal fluid revealed increased pressure but no other pathologic changes. The author thinks that the meningeal symptoms were of tuberculotoxic or allergic origin, in that the allergy of the organism was suddenly increased in response to the intracutaneous injection of tuberculin. He evaluates the significance of these observations in connection with tuberculous meningitis and points out that the anamnesis frequently reveals an erythema nodosum in cases of tuberculous meningitis.

**Elimination of Gonadotropic Hormone Formed in Hypophysis.**—Anselmino and Hoffmann point out that the assumption of the placental origin of the gonadotropic substances in the blood and urine of pregnant women has found wider acceptance in recent years. However, a number of authors have also called attention to the different gonadotropic action of prehypophyseal preparations and of the extracts of pregnancy urine. The authors say that, although it cannot be doubted that the gonadotropic substances which appear in such large quantities in the blood and urine of pregnant women are of placental origin, a number of investigations indicate that the pregnancy urine eliminates also gonadotropic hormones that have been formed in the hypophysis. The authors describe their own investigations on the gonadotropic hormone of hypophyseal origin in the urine during normal pregnancy, during hyperemesis gravidarum and during eclampsia. They show that with the method of Evans and his collaborators it is possible to demonstrate in the urine of a number of women during the early part of pregnancy small amounts of gonadotropic hormone that has been formed in the hypophysis. This observation demonstrates the contradictory results of the action of gonadotropic substance on hypophysectomized animals. In patients with hyperemesis gravidarum, gonadotropic hormones of hypophyseal origin appear in the urine regularly in increased quantities, whereas in the urine of eclamptic patients the hypophyseal gonadotropic hormones cannot be demonstrated. The authors reach the conclusion that the blood and urine of patients with hyperemesis or with eclampsia contain unphysiologically large quantities of gonadotropic substances, which in the patients with hyperemesis are mostly, and in those with eclampsia exclusively, of placental origin.

**Rupture of Liver in the New-Born.**—After pointing out that hepatic rupture is a comparatively rare birth injury, Schmitt reviews the literature on this problem, particularly the report of Hedrén, who maintained that the parenchymatous ruptures should be differentiated from the subcapsular hepatic hemorrhages. In the true ruptures the parenchyma is injured, whereas the subcapsular hemorrhages signify tearing of the hepatic capsule. In the case reported by Hedrén, the injury of the hepatic parenchyma developed in a spontaneous delivery, a possibility that had been denied by Kratter. In discussing the causes of subcapsular hemorrhages as well as of the parenchymatous injuries, the author again cites Hedrén, who believed that the pressure exerted during delivery on the right costal arch and on the abdominal wall might play a part but in addition to this there must be other factors, such as an overfilling of the liver with blood as the result of asphyxia. The author reviews reports of other authors. He cites Genell, who reports the history of a woman with obliquely contracted pelvis, who twice gave spontaneous birth to apparently mature and healthy infants, but each time the child died as the result of hepatic rupture. After reviewing several other reports, the author describes three cases that were observed at his clinic and prove that hepatic rupture and subcapsular hepatic hemorrhages may develop in spontaneous and in artificially terminated delivery. The true ruptures are the rarer forms of injury. Some authors recommend suture, while others consider treatment useless.

#### Treatment of Fractures of Humerus in the New-Born.

—Wahl shows that Spitzky's "high back splint," which is the "low back splint" (which is used for fractures of the clavicle), is designated also as "transverse back splint," causes a severe torsion of the distal end of the fracture of the humerus and effects curative results that are undesirable from the anatomic as well as from the functional point of view. In the two cases the author gives clinical and roentgenologic proofs of a severe peripheral dislocation of almost 90 degrees rotation. On the basis of these unfavorable experiences and of theoretical analysis he reaches the conclusion that Spitzky's "high back splint" should not be applied for the treatment of fractures of the humerus in the new-born. He advises that in fractures of the shaft of the humerus as well as in case of detachment of the proximal epiphysis the attachment of Desault's bandage should be preceded by the application of a splint consisting of a narrow strip of aluminum, which is bent in such a manner that it can be placed from the back and the outside on the padded arm. At the level of the fracture the strip should be bent anteriorly and inward, so that the convexity of the strip will counteract the rotation.

#### Action of Eclampsia Serum in Allergy Experiment.

According to Junghans, Knepper succeeded in producing the characteristic eclamptic changes in the liver and kidneys of rabbits by the simultaneous injection of horse serum and of solution of posterior pituitary. His own experiments were undertaken in order to examine the action of eclampsia serum in the allergy experiment on pregnant animals. Studies of other investigators had revealed that a single injection of eclampsia serum produces no anatomic changes in the organs. The author injected subcutaneously into pregnant rabbits 2 cc. of sterile, inactivated serum from eclamptic women, repeating this procedure at intervals of five or six days. Beginning about three weeks after the first subcutaneous injection, the animals were given repeated serum injections into the vein of the ear. Some of the animals developed anaphylactic shock from which they recovered. At the end of the pregnancy the animals were

## TREATMENT OF MENSTRUAL MIGRAINE

WITH SMALL DOSES OF GONADOTROPIC  
EXTRACT OF PREGNANCY URINE

WILLIAM M. MOFFAT, M.D.

SANTA BARBARA, CALIF.

As Critcheley and Ferguson<sup>1</sup> said before the Harveian Society, "Migraine has been the happy hunting ground of the theorist, and the problem has been attacked by representatives of all branches of medicine. Each in turn has discovered in migraine phenomena pertaining to his own specialty . . . has hit upon the true nature of the malady . . . has found the infallible remedy. Obviously, such mutually exclusive viewpoints cannot all be entirely correct, and the multiplicity and diversity of the hypotheses suggest that the problem is more complex than imagined, and probably one which presents a number of facets."

It is my purpose in this paper, which records the results of a hitherto unreported method of treatment, to shed more light on the nature of this puzzling malady and perhaps also to add something to our relatively meager knowledge of the gonadotropic factor extracted from pregnancy urine.<sup>2</sup> However, it must be kept in mind that only one of the many facets of the migraine problem is considered.

Space will not permit any detailed discussion of the theories as to the cause of migraine. Since Riley's<sup>3</sup> monumental review of the subject in 1932, excellent articles have been published by Critcheley and Ferguson<sup>1</sup> in England and by Bassoe<sup>4</sup> in America in which migraine is discussed in all its aspects, including the endocrine. It is generally believed that there is at least an endocrine factor in the production of menstrual migraine. Even allergists such as Andresen<sup>5</sup> postulate a "reaction resulting from sensitization to one of the products elaborated at the time of menstruation." But in the endocrine field again nearly every gland has at one time or another been accused of being overactive, underactive or dysfunctional, yet treatment directed at the supposed cause has rarely been as successful in the hands of others as the original report gave them hope to expect. Perhaps an exception should be made in the case of Thomson,<sup>6</sup> who in 1932 reported twenty-five cases of headache occurring particularly at menstruation, in seventeen of which some abnormality of the sella turcica was demonstrated radiologically, nine of them showing complete calcification of the interclinoid ligaments. He believes, as was previously suggested by Pardee<sup>7</sup> and by Timme,<sup>8</sup> that the periodic headaches were caused by a swelling of the pituitary gland in this confined space. He also suggested that in cases in which no sellar abnormality could be demonstrated radiologically there might possibly be a complete membranous covering without ossification. Since the admin-

istration of estrogen has been shown in animals to reduce the size of the pituitary body, Thomson used this substance in the treatment of menstrual headache. It is debatable whether this view of the cause of the headaches is tenable, but there is no question as to the results of his treatment with estrogen. Of the twenty-five cases he reported ten completely relieved, six markedly improved, five slightly improved and four in which there was no apparent effect. It is of interest to observe, however, that two of Thomson's patients, in whom estrogen therapy failed, were subsequently relieved by injections of extracts of the corpus luteum.

Then too there is the work of Blakie and Hossack,<sup>9</sup> who reported a series of twenty cases of menstrual migraine all of which were relieved by treatment with estriol complex (emmenin).

Stieglitz,<sup>10</sup> in describing the migraine physique, gives a remarkably accurate description of the physical appearance of the woman suffering from ovarian deficiency without, however, mentioning the similarity, and, in tabulating the characteristic manifestations in his 100 cases, lists cases under menses as follows: normal 6 per cent, marked intoxication 91 per cent, dysmenorrhea 63 per cent.

Finally there is the laboratory evidence offered by Riley, Brickner and Kurzrok,<sup>11</sup> who over a prolonged period made daily hormone studies on the urine of thirteen patients—eleven females and two males—suffering from migraine. In all the women of menstrual age the excretion of estrogen was far below normal, though there was no relationship between variations in the excretion of estrogen and the occurrence of headache. The whole group of patients experienced a total of twenty-nine attacks of migraine during the investigation and in twenty instances the headache was preceded or accompanied by the appearance of gonadotropic substance in the urine. Generally it appeared from one to six days before the headache and disappeared on the day of the attack. Occasionally it appeared without the subsequent development of headache. In two patients presenting status migrainicus the excretion of gonadotropic substance was practically uninterrupted. Nine female patients were injected with 2 cc. of gonadotropic factor from the urine of pregnancy and in seven an attack of migraine developed within four to twelve hours. The authors conclude: "The presence of [gonadotropic substance] in the urine is definitely related to the occurrence of migrainous seizure. Substantiation is given to the hypothesis that ovarian and presumably hypophyseal activities are closely related to the occurrence of migraine."

## REPORT OF CASES

CASE 1.—An unmarried woman, aged 38, complained of severe headache either unilateral or bilateral, accompanied by nausea and vomiting, which recurred every three weeks at the time of her menstrual period and lasted three or four days. She had been constantly under treatment for many years. The sinuses had been operated on three times and the uterus suspended twice. Antiallergic treatment had been carried out over a long period. For the past seven years she had been on endocrine therapy including anterior pituitary extract, solution of posterior pituitary and estrogen by hypodermic injection, and thyroid, pituitary and various ovarian preparations by mouth. In July 1933 she was still suffering from the headaches. At

## GONADOTROPIC HORMONE IN THE DIAGNOSIS OF CHORION- EPITHELIOMA

BERNHARD ZONDEK, M.D.  
JERUSALEM

The hormonal pregnancy test is important not only for the early diagnosis of normal pregnancy but also for the early recognition of pathologic changes in the placenta (hydatidiform mole, chorionepithelioma). In a lecture at the Viennese Biologic Society on April 15, 1929, I<sup>1</sup> reported that the excretion of gonadotropic substance in the urine in cases of hydatidiform mole is from two to three times as great as in normal pregnancy and that the concentration of this principle in the fluid of the mole is greater than in its wall. Thus I demonstrated that the production of gonadotropic substance in hydatidiform mole is greater than in normal pregnancy. In 1930 Robert Meyer<sup>2</sup> reported that the hormone excretion is also increased in chorionepithelioma. In a case of chorionepithelioma of the kidney a positive pregnancy test was obtained with only one-seventieth cubic centimeter of urine. Aschheim<sup>3</sup> had previously ascribed the formation of luteal cysts in the ovary in hydatidiform mole and chorionepithelioma to a secretion of the anterior pituitary. The question remained whether in hydatidiform mole and in pregnancy more hormone is actually produced or whether more is just retained.

That the demonstration of an increased excretion of gonadotropic substance in the urine is important for early diagnosis of chorionepithelioma is now acknowledged unanimously in the literature. Physicians are obliged to have the urine of every woman who has suffered from hydatidiform mole assayed for this factor. While the increased excretion of gonadotropic principle usually ceases about one week after delivery of a normal placenta, it may continue for from four to twelve weeks following discharge of a hydatidiform mole. I recommend the following procedure: In case the pregnancy test is still positive six weeks after the discharge of a hydatidiform mole and the content of gonadotropic factor in the urine increases progressively during this time, it is probable that a chorionepithelioma is present. Quantitative assay for gonadotropic substance is especially important in such cases. If a positive pregnancy test can be obtained at the same time with spinal fluid (undiluted or diluted), this is further confirmation of the diagnosis. As a further diagnostic

safeguard a carefully performed exploratory curettage is necessary. In case histologic examination of the curettage material is doubtful, which may sometimes be the case, assay of the urine for gonadotropic factor is of greater significance in the diagnosis than the histologic examination.

In case the pregnancy test has become negative following discharge of the hydatidiform mole, the patient's urine should be assayed at monthly intervals. If the negative reaction becomes positive again, the following possibilities must be considered: either there is a new pregnancy or the patient has a chorionepithelioma. I wish particularly to emphasize the possibility of a new pregnancy, because chorionepithelioma is usually the first thing thought of in these cases. There is always the danger of interrupting a normal pregnancy or even of extirpating the pregnant uterus of a healthy young woman. If gynecologic examination does not establish the presence of a new pregnancy, quantitative urinary assay for gonadotropic substance should be performed. In normal pregnancy the excretion of this factor is much less than in chorionepithelioma.<sup>4</sup>

**Method.**—Examination of urine and spinal fluid is performed with the methods usually employed for the pregnancy test. The content of gonadotropic substance being far greater in chorionepithelioma than in normal pregnancy, the urine as well as the spinal fluid must be correspondingly diluted with water. In a normal pregnancy reactions II and III ("blutpunkte" and luteinization) are obtained in mice with from 1.2 to 2.4 cc. of urine. In chorionepithelioma 0.001 cc. may be sufficient. Titration is performed in such a way that the amount of fluid to be examined is injected into infantile mice, divided in six doses in the course of forty-eight hours.

**Tissue Assay.**—For the diagnosis of chorionepithelioma, qualitative and quantitative tissue assay for gonadotropic substance is also important. This procedure<sup>5</sup> which I proposed in 1930, often gives valuable information; for this reason I am presenting it here as it is only rarely employed.

(a) **Implantation.**—The tissue to be examined is finely cut and amounts of up to 200 mg. are implanted into the femoral musculature of two infantile mice. This is the method by which I demonstrated the gonadotropic function of the anterior pituitary in July 1925. The implanted foreign tissue disintegrates in the musculature of the mouse and is absorbed.

(b) **Extraction.**—As one cannot be certain whether or not complete absorption occurs, which may lead to quantitative errors, I prefer the extraction method; this is performed as follows: The tissue to be examined is finely minced and left in ether for twenty-four hours; toxic substances are extracted by ether from tissue (as well as from blood and urine)<sup>6</sup> but not gonadotropic substance. The ether is then poured off and the tissue very energetically mixed to a mash with the addition of from two to three times the amount of sterile sea sand and ten times the amount of distilled water. The mixture is shaken for several hours (at least six, preferably twelve) in a shaking

X-ray studies of the sella turcica were made in eleven cases. Four of these showed complete bony bridging of the interclinoidal space and three others showed small sellae almost bridged over, while only four were normal. It is not within the scope of this paper to enter the controversy concerning the possible connections between abnormal sellae and menstrual headaches, and this observation is entered merely as a matter of record.

#### TECHNIC EMPLOYED

What is here meant by a month's course of treatment? After experimenting with gonadotropic factor from pregnancy urine for the preceding two years, finally, early in 1933, I evolved the following routine: Beginning on the fifth to the seventh day after the onset of the menstrual flow a small dose, usually ranging from 2 to 6 rat units, is given; the dose is slightly increased daily until the tenth day, then rapidly increased, reaching a maximum of from 50 to 125 rat units on the fourteenth day, after which from 25 to 50 units is given daily until the onset of the next menstrual period.

#### COMMENT

The theory on which this routine was originally based was erroneous, as will appear later in the discussion, but the fact of relief of menstrual migraine remains. Psychic effect can be ruled out first because of the number of patients involved, all with a special type of migraine, and, secondly, because most of them had been previously treated without relief over a long period of time, some of them by me, and were pathetically accustomed to hypodermics. Patient 1 had some time previously been given 50 units of a similar pregnancy urine preparation three times weekly for four weeks without benefit.

What then is the action of gonadotropic substance from pregnancy urine in relieving menstrual migraine? At the time of its adoption the foregoing routine of administration was based on the then current theory<sup>12</sup> that small doses early in the menstrual cycle produce follicular stimulation and that the large doses induce ovulation and luteinization at the time they should normally occur, after which only small doses are needed to maintain luteinization. Viewed in the light of later experimentation this theory is probably invalid, since in the macaque monkey no ovarian stimulation is ever obtained,<sup>13</sup> and Geist<sup>14</sup> from his preoperative experiments on women concludes that "apparently there is no stimulation of the follicle, rather an arrest of follicular development." However, as Engle<sup>15</sup> pointed out, the macaque monkey never at any time even during pregnancy excretes gonadotropic substance in the urine and hence the analogy to the human being must not be too closely drawn. Also in Geist's experiments enormous doses of gonadotropic substance from the urine of pregnancy<sup>16</sup> varying from 600 to 2,200 rat units were given over a period varying from thirty-six to 100 hours, as much as 600 rat units being given in one day in divided doses. This is far in excess of any therapeutic dose, but even so it is of interest that Geist records that the intensity of reaction in the ovary seems to bear a direct relationship to the amount of substance injected. The effect of varying therapeutic doses of gonadotropic

factor on the human ovary needs further study before dogmatic statements can be made.

Moreover, recent experimentation led by Evans<sup>16</sup> and Mazer and Katz<sup>17</sup> has shown that the combination of gonadotropic factor from pregnancy urine and the "synergist" from the anterior pituitary produces much greater ovarian stimulation than could be accounted for by the simple sum of the two extracts. Is it not probable, then, that the women in the present report had sufficient pituitary activity of their own to obtain the clinical effect of this combined therapy? The fact that they were all menstruating more or less regularly shows that they did not have a severe form of pituitary deficiency. With this amendment to the original theory, it would seem that this may be a valid hypothesis.

This fits in well with Riley, Brickner and Kurzrok's conclusions that the fundamental mechanism in the production of migraine is "one of hypophyseal hyperfunction or of ovarian hypofunction." For if the technic employed stimulates the ovary to a greater production of estrogen, this through its claimed depressant action on anterior pituitary gonadotropic hormone production would correct a previously existing ovarian hypofunction and anterior pituitary hyperfunction and by restoring the balance between these hormones remove the cause of the migraine attack.

One other possibility must be mentioned. Perhaps lending some support to the allergist's view of migraine is the fact that of the seventeen women four, or 24 per cent, gave a family history of allergy; eight, or 47 per cent, had themselves one or more of the accepted manifestations of allergy; four, or 24 per cent, gave a family history of migraine, and two, or 12 per cent, had a family history of epilepsy. If the migraine attacks were due to a sensitization to gonadotropic factor, this technic of beginning with a small dose of gonadotropic factor extracted from the urine of pregnancy and increasing very gradually to the larger doses may have simply desensitized the patients to gonadotropic factor and thus prevented their attacks. On the other hand, here again it may have been an ovarian stimulation which prevented the excessive or unopposed production of gonadotropic substance at the time of menstruation.

Still unexplained, however, and seemingly ignored in published papers on the estrogenic-gonadotropic balance in migrainous women are two facts: first, that so many women subject to migraine have no attacks during pregnancy, when there is an excess of both the luteinizing factor and estrogen, and, second, that in most women the migraine attacks cease after the menopause, when there is little or no estrogen but an excess of follicle stimulating factor. The answers to these problems will have to await further study.

#### CONCLUSION

It must be reiterated that I am considering only one of the many facets of the migraine problem and am dealing with a highly selected group of patients afflicted with a particular type of headache. With this in mind it seems fair to conclude that the results here reported tend to confirm the hypothesis that a leading factor in the production of menstrual migraine is either an ovarian or an anterior pituitary dysfunction, and probably an ovarian hypofunction or pituitary hyperfunction.

readily. In the posterior vaginal wall there was a necrotic spongy, fetid tumor the size of an egg. The uterus was enlarged, corresponding to a three months' pregnancy. A piece of the tumor was taken with a curet from the uterus; the histologic examination showed an indisputable chorionepithelioma.

In this advanced case, with metastases in the vagina, the diagnosis was easily established clinically. The urine assay confirmed the diagnosis. The content of gonadotropic substance was exceedingly high, such as I had not observed before (more than 1,000,000 mouse units of follicle-stimulating and luteinizing hormone per liter of morning urine). The blood also contained an abundant supply of gonadotropic substance (500,000 mouse units of follicle-stimulating factor and 250,000 mouse units of luteinizing principle per liter of serum). In this case the spinal fluid was also examined (40,000 mouse units of follicle-stimulating factor and 6,666 mouse units of luteinizing substance per liter).

**Tissue Assay.**—As the vaginal metastasis was already necrotic, its content of gonadotropic principle was very small (600 mouse units of follicle-stimulating factor per gram. No luteinizing effect was obtained at all. In the uterine tissue, which also showed necrosis, I found 1,500 mouse units of follicle-stimulating substance and 300 mouse units of luteinizing factor per gram of tissue.

Two weeks after admission to the hospital the patient died with high fever and cerebral symptoms.

**CASE 3.**—This case has been reported elsewhere.<sup>11</sup> I mention it here because of the data furnished by tissue assay and investigations of the pituitary. This case was referred to me by Dr. James Heyman of Radiumhemmet during my stay in Stockholm. The patient was a woman, aged 27, in whom a hydatidiform mole of a size approaching the fourth month of pregnancy had been removed in November 1933. Jan. 1, 1934, severe hemorrhage occurred. In the introitus vaginae there was a plum-sized spongy, grayish-black, friable tumor which bled easily; a similar tumor was found in the posterior vaginal wall. The os uteri was open three finger breadths and was filled with an egg-sized, spongy, friable tumor. Histologically this was an indisputable chorionepithelioma. It metastasized rapidly, and death occurred Jan. 27, 1934. Autopsy showed metastases in the liver and in the lung.

Assay of the urine some days before death occurred had shown a value of 100,000 mouse units each of follicle-stimulating and luteinizing factors per liter. The blood contained 10,000 mouse units of each per liter. A quantitative assay of the primary tumor was impossible because of extensive necrosis, but assay of the metastasis in the lung gave 100 mouse units each of follicle-stimulating and luteinizing factors per gram of fresh tissue (extraction method).

The pituitary gland was impressive macroscopically by its size. It was cut through sagittally; one half was examined histologically and the other half assayed biologically. The anatomic examination (performed by Professor Berblinger) revealed typical pregnancy cells in the posterior part of the anterior lobe; otherwise the cellular structure was normal. Assay of the pituitary was performed by the implantation method. Although ordinarily the pituitary from cases of chorionepithelioma is found to be free of gonad-stimulating effect, in this case gonadotropic substance was present; however, only a follicle-stimulating effect was obtained and this was less than that of the normal gland. About ten times the normal amount of gland was necessary (i. e., 50 mg.) to produce follicular maturation. A luteinizing effect could not be obtained even after implantation of 100 mg. of tissue.

#### COMMENT

The three cases here reported demonstrate the value of the hormonal pregnancy test in the diagnosis of chorionepithelioma. The differential diagnosis between normal pregnancy and hydatidiform mole and chorionepithelioma is rendered possible by the fact that production and excretion of gonadotropic substance is greatly increased in the latter instances. Production of gonadotropic principle is greatest at the beginning and in the early months of pregnancy; it diminishes in

the latter months (Aschheim and Bernhard Zondek). In early pregnancy the content of this substance amounts to an average of 10,000 mouse units per liter of blood and from 5,000 to 30,000 mouse units per liter of morning urine. Production of gonadotropic principle may also be increased in gestation toxicosis (G. van S. and O. W. Smith<sup>12</sup>) in such a fashion that amounts near those obtaining in hydatidiform mole may be discharged in the urine. The increased excretion therefore indicates the presence of a hydatidiform mole only if toxemia of pregnancy can be excluded. The symptoms of toxicosis are clinically so clear that an error should not arise from this source. Chorionepithelioma does not occur until weeks or months have passed after discharge of the placenta or a hydatidiform mole. As I have already mentioned, differential diagnosis of a new normal pregnancy must always be considered.

The pregnancy test is based on the occurrence of blood points (reaction II) or corpora lutea (reaction III) in the ovaries of mice; that means on the presence of the luteinizing principle ("prolan B"). Pregnancy is diagnosed when, by injection of undiluted urine, (six

Gonadotropic substance in urine in case 1. Solid line, follicle-stimulating factor; broken line, luteinizing principle. Postoperative treatment: A, intravaginal radium irradiation; high voltage roentgen therapy of the pelvis. B, C, high voltage roentgen therapy of the lungs.

injections of from 0.2 to 0.4 cc.) reaction II or III can be obtained; that is, if at least from 416 to 832 mouse units of luteinizing factor is present in a liter of morning urine. The presence of this quantity of follicle-stimulating factor ("prolan A") is not sufficient for the diagnosis of pregnancy, as such amounts also occur in urine apart from pregnancy; namely, in disturbances of the ovarian function<sup>13</sup> and in certain tumors.<sup>13</sup> While working out the pregnancy test I observed, on the occasion of a wrong diagnosis (mistaken for myoma), that reaction I (follicle maturation) may not be used for the pregnancy test; the margin of error would amount to 10 per cent if reaction I were considered a positive test.

In chorionepithelioma the production of follicle-stimulating factor may be so immensely increased, and such immense amounts of hormone may be present in the urine, that the occurrence of follicle maturation in the test animal may also be used for diagnosis to a certain degree, but only when at least 500,000 mouse units of follicle-stimulating factor is present in a liter of

10 ALKALINE URINE	15	1.80 / 5.13	80.00

Summary of results under ten test conditions.

The average number of ruptured follicles was 1.75 and the average number of unruptured follicles was 2.5.

(e) When one injection of 5 cc. of blood serum was made and the animal killed thirty-six hours after the injection, the test was positive in eleven instances. In six cases there were ruptured follicles, unruptured follicles also being present (54.5 per cent). The average number of ruptured follicles was 0.82 and the average number of unruptured follicles was 5.82.

2. *Age and Weight of Test Animals.*—It is said to be desirable to use rabbits that are at least 6 months old. Since we did not raise our own test animals we had no way of being certain how old each animal was. Therefore we depended on the weight. Here again consideration must be taken of the fact that different breeds mature at different weights. It is often stated that the test animal should weigh at least 4 pounds (1,814 Gm.).

We ran a series of twenty-six does of three breeds (New Zealand, Belgian and Chinchilla) in which no animal weighed more than 3 pounds (1,363 Gm.). The weights ranged from 1,000 to 1,360 Gm. and the average weight was 1,272.88 Gm. Only two of the animals weighed less than 1,200 Gm. (1,000 and 1,025 Gm.).

Fourteen of these animals were subjected to the Friedman 10-10 modification and eight to the original Friedman test; four were given one 10 cc. injection and killed in thirty-six hours.

The test was positive in every case. In fourteen instances there were both ruptured and unruptured follicles. In twelve cases there were no ruptured follicles, though unruptured follicles were present. Unruptured follicles were present in every case.

The average number of ruptured follicles was 1. The average number of unruptured follicles was 5.85.

Ruptured follicles were present in 53.84 per cent of the cases. For the purpose of comparison, twenty-six results with rabbits weighing more than 3 pounds (from 1,380 to 2,700 Gm.; average, 1,754.61 Gm.) were averaged. In eleven the Friedman modification was used, in seven the original Friedman test, in two the injection of one 10 cc. quantity killing the animal in thirty-six hours, in three 2.5 cc. blood serum and in three 5 cc. of blood serum. The average number of ruptured follicles was 1.77, unruptured 7.07, and in 88.48 per cent ruptured follicles were present. It can readily be seen that quantitatively the results were better with the heavier rabbits.

3. *Specific Gravity of Urine.*—Selecting eight instances with urines of specific gravity each of 1.010, four with 1.008, one with 1.007 and one with 1.006, we found that the test was positive in each case for an average of 1.28 ruptured follicles, 7.57 unruptured and with ruptured follicles in 64.28 per cent of the tests. In the 1.007 specimen there was only one ruptured follicle and none unruptured. In the 1.006 specimen there were no ruptured follicles and five were unruptured. The tests were negative in four instances with specific gravities of urine from pregnant women of 1.007, 1.006, 1.005 and 1.005.

For comparison, fourteen tests were selected in which the specific gravity of the urines ranged from 1.014 to 1.024, with an average of 1.018. The average number of ruptured follicles was 1.5 and of unruptured follicles 7.56, and ruptured follicles were present in 78.57 per cent of the tests.

While this record is not much better than that of the 1.006 to 1.010 group, the negative tests in the 1.005 to 1.007 group are significant.

4. *Reaction of Urine.*—In fifteen of our tests the reaction of the urine was alkaline. The average number of ruptured follicles was 1.8 and of unruptured 5.13, and there were ruptured follicles in 80 per cent of the cases. These results do not compare unfavorably with those given in 1 a and 1 b.

This is in accordance with the observations of Elden and Fellows,<sup>2</sup> who found that although the anterior pituitary-like hormone of the urine is most potent at a  $pH$  of from 6.1 to 7.3 and that the potency is reduced by alkali content, their observations in no way affected the Friedman modification of the Aschheim-Zondek test because large quantities of urine (from 5 to 10 cc. on each injection) are used.

Some of our test animals died during or immediately after injections and we considered the possibility of alkalosis as a cause of death. In order to test this point seven does were injected with alkaline urines of  $pH$  from 7.4 to 8.4, but none of them showed any untoward effects from the injections.

#### CONCLUSIONS

1. The presence of one or more ruptured follicles in either ovary or both ovaries in this test constitutes a positive reaction. The presence of several unruptured hemorrhagic follicles in both ovaries (usually two or more in each ovary) is also a positive reaction. Unruptured hemorrhagic follicles are red; black follicles of all sizes have no significance and must be disregarded. (Corpora lutea visible to the naked eye do not develop within forty-eight hours, nor can they be seen with the

in the tumor tissue in a disgerminoma, but it was present in the chorionepitheliomatous areas in large quantities. One can also get some idea of the malignancy of a particular tumor by means of these assay methods: hormonal tissue diagnosis and hormonal urine analysis. The latter seems to me to be confirmed by the investigations of Ferguson.<sup>19</sup> I am, however, skeptical whether the anatomic structure of a tumor can be ascertained by the hormone excretion as accurately as Ferguson appears to believe.

It is interesting that both in normal pregnancy and in cases of chorionepithelioma the pituitary gland has been found to be free of gonadotropic substance (Philipp, Zondek, Fels). In contrast to these observations, assay of the anterior pituitary in case 3 indicated the presence only of follicle-stimulating but not of luteinizing factor. But the content of the former was diminished by 90 per cent. The question has frequently been discussed whether the large increase of gonadotropic hormone occurring in pregnancy has its origin in the pituitary gland or in the placenta. Because in pregnancy this substance is not found in appreciable quantity in the anterior lobe but does occur in large amounts in the placenta, the conclusion has been drawn that it originates in the placenta. It is difficult to understand why the function of the anterior pituitary should so change in pregnancy as well as in chorionepithelioma and malignant testicular tumors. The reduced content of hormone in the gland does not in my estimation prove absence of function. It would exceed the scope of the present paper to go into this question which I have considered elsewhere.<sup>20</sup> One point may be mentioned here, however. Hohlweg and Junkmann<sup>21</sup> and Schoeller<sup>22</sup> have suggested the existence of a cerebral sexual center, which is regulated by the estrogenic hormone. Reduction in or absence of estrogenic hormone would lead—by influence on the center—to an increased activity of the pituitary gland; increased production of follicular hormone would in the same way inhibit secretion by the anterior lobe. The rise in the level of the estrogenic hormone in pregnancy so affects the sexual center that the anterior pituitary ceases its production of gonadotropic hormone. However, in chorionepithelioma and in malignant testicular tumor the anterior pituitary contains little or no gonadotropic hormone. In these conditions the amount of estrogenic substance is not increased; consequently anterior pituitary function cannot be interrupted in these instances by estrogenic hormone. If the negative hormone finding in the pituitary of pregnancy is explained by the increased level of estrogen, the negative hormone finding in the pituitary gland in chorionepithelioma and in testicular tumor is inexplicable on this basis. The absence of gonadotropic hormone in the pituitary of pregnancy cannot be considered proof of the existence of a sexual center controlled by estrogenic hormone. As I have demonstrated recently by experiment,<sup>23</sup> the function of the anterior pituitary (gonadotropic hormone, growth hormone) can be impaired by estrogen; however, the production of gonadotropic hormone in the cells of the anterior pituitary is not inhibited, but only delivery of the hormone into the blood stream.

## SUMMARY

1. In the pathologic placenta (hydatidiform mole, chorionepithelioma) the production and excretion of gonadotropic substance may be immensely increased. The hormone appears in greatly increased amounts in the blood, urine and spinal fluid.

2. A diagnosis of hydatidiform mole cannot be considered as established unless, in repeatedly performed examinations, at least 200,000 mouse units of luteinizing principle is found in the urine and, in addition, a positive luteinizing reaction is obtained from the spinal fluid, preferably diluted. It is necessary to rule out toxemia of pregnancy, as in this condition large amounts of luteinizing substance are also excreted in the urine. However, in the latter case only a follicle-stimulating effect is obtained in spinal fluid.

3. If the pregnancy test still remains positive six weeks after the discharge of a hydatidiform mole, and if the content of gonadotropic substance in the urine has progressively increased in this period, it suggests a diagnosis of chorionepithelioma particularly if a positive reaction is also found in the spinal fluid. For confirmation of the diagnosis, exploratory curettage is necessary. If the result of the histologic examination is doubtful, the result of biologic assay of the urine and the spinal fluid is of great significance.

4. In case the pregnancy test has become negative after the discharge of the hydatidiform mole and once more becomes positive within some time there is either a new pregnancy or a chorionepithelioma. Differential diagnosis must be established by clinical observation and, in addition, by quantitative urine assays.

5. The assay of urine for gonadotropic substance is of importance not only for diagnosis but also for prognosis in chorionepithelioma. If the pregnancy test has become negative following therapeutic measures, and if luteinizing substance occurs once more in the urine, this indicates that the malignant process is proceeding. Apparent clinical improvement may often be deceiving in such cases.

6. A considerable reduction in excretion of follicle-stimulating hormone occurring suddenly without therapeutic measures is clinically a threatening sign, although when this occurs following therapy it is usually considered a favorable sign.

7. As the normal placenta is rich in gonadotropic material, the presence of 800 mouse units of luteinizing substance per gram of fresh tissue obtained by curettage must be established before one can diagnose a malignant condition. If 100 mouse units per gram is found in extra-uterine tumors, this indicates that the tumor is a metastasizing or extragenital chorionepithelioma.

8. Chorionepithelioma of the testicle or testicular teratoma with chorionepitheliomatous inclusions lead to a strongly increased production and discharge of follicle-stimulating and luteinizing factors. This increased excretion may also occur occasionally with other testicular tumors. It is absent in disgerminoma. Tissue assay of testicular tumors furnishes valuable information as to the nature of the tissue. Disgerminomas do not contain gonadotropic substance; the chorionepitheliomatous parts contain much of this factor.

9. The anterior pituitary in normal pregnancy as well as in chorionepithelioma and in malignant testicular tumor contains little or no gonadotropic hormone.

and enjoying good health, and there is no void in the skull tables. On account of the profuse hemorrhage, which could hardly be controlled, it is unlikely that she would have survived had the operation been carried to completion.

The published roentgenograms of proved cases of hemangioma of flat bones have for the most part shown strikingly similar patterns of density. This was nicely brought out in Bucy and Capp's<sup>4</sup> study of their own cases and their review of previously recorded cases. It has been my privilege to see a roentgenogram of one of their cases, in which there was a large sunray hemangioma of the scapula, six years after their report. The growth is no larger and the bone is of increased density on the roentgenograms, apparently because of a greater deposit of bone. These changes occurred rapidly following roentgen therapy and no growth has been noted since the first course of roentgen therapy.

The same change seems to have occurred in the case here reported, but at an unusually slow rate, requiring fifteen years (figs. 2 and 4) without roentgen therapy. It seems most likely that the tumor would have resolved into a small solid mass of bone early in its course had roentgen therapy been given early when the tumor was predominantly vascular. It is interesting, in reviewing the published cases, to find in most instances when hemangiomas were mistaken for malignant neoplasms that flat bones were involved. Sarcoma of flat bone is less prone to present a sunray appearance. Sometimes a coral reef pattern of density is presented by heman-

Fig. 4.—Anteroposterior view at 26. Lighter exposure shows coarse bone spicules maintaining the "perfect" sunburst pattern.

gioma and only infrequently has there been erosion of bone by pressure producing a smooth defect. When a smooth defect is produced, the roentgenogram is of little value in differentiating hemangioma from other large primary tumors within the skull. Occasionally hemangioma, like meningioma, burrows its way along the skull tables, but when spicule formation has taken place in meningioma the spicules most often do not radiate from a central point but are more parallel and cover a larger area on the skull.<sup>2</sup>

Tumors with radiating spicules of bone have been found most often in roentgenograms of long bones and have proved to be malignant neoplasms (osteogenic sarcoma). Likewise, hemangiomas of long bones have produced evenly spaced divergent trabeculations, as well as the so-called soft soap bubble appearance, loculations with paper-like thin walls. In both hemangioma and sarcoma the periosteum is elevated gradually by the new growth, and spicules of bone are formed which elongate at right angles to the advancing periosteum. Usually in sarcoma the growth has occurred too rapidly

this time an x-ray study of the sella turcica showed a complete bony bridging between the anterior and posterior clinoids. Daily treatment with gonadotropic factor from pregnancy urine was instituted. Ten days later she menstruated and complained of only a slight headache. The next month routine therapy, as described later, with the same preparation was given and she had a period entirely without symptoms. Treatment was continued during the succeeding nine months with the frequency of the dose gradually reduced. The menstrual cycle increased to twenty-six or twenty-seven days, very occasionally with a slight transient headache but usually with none at all. She then discontinued treatment for four months but since the headaches returned and she found that a single small dose of gonadotropic factor from pregnancy urine (18 rat units) would relieve them, she has taken this amount about twice a month during the past year.

CASE 2.—An unmarried nurse, aged 43, whose headaches had been growing progressively more severe for several years, was given anterior pituitary extract and solution of posterior pituitary with no effect on her headaches. For about two years she was considerably relieved by injections of a commercial ovarian extract. For the last six months her headaches had failed to be so relieved, had become practically continuous and were so severe that she was taking daily from 3 to 4 grains (0.2 to 0.25 Gm.) of codeine in addition to large doses of acetylsalicylic acid and aminopyrine. She was given daily injections of estrogen but her headaches became so much more severe that this was discontinued and from Jan. 6 to 22, 1934, she was given daily injections of gonadotropic factor extracted from the urine of pregnancy. From January 9 until July she remained free from headaches. When last seen in May 1936 she was still comfortable, though she had taken an occasional short course of treatment with gonadotropic factor from the urine of pregnancy when the headaches appeared to be returning.

CASE 3.—A married woman, aged 44, complained that her periods since their onset at the age of 17 had always been accompanied by a severe headache, either unilateral or bilateral, beginning from three to four days before the flow and associated with nausea, faintness, nervousness, the passing of urine every few minutes, and loose movements. For many years she had been given thyroid and ovarian and pituitary preparations without relief. In March 1933 she was given estrogen for two months with considerable relief, but not freedom, from headaches. In May she was changed to gonadotropic factor extracted from the urine of pregnancy five days before the onset of menstruation, which was accompanied by a three day headache. The following month she had a full course of the gonadotropic factor, which has since been continued in reduced dosage, and she has gone three years with only an occasional slight transient headache except on one occasion when she had been without treatment for three months.

CASE 4.—A married woman, aged 31, just before the appearance of the catamenia at 10½ years had the first of many attacks of unconsciousness diagnosed at various times as epilepsy and major hysteria. These attacks had disappeared in recent years but had been replaced by severe headaches occurring chiefly preceding her menstrual periods, which were slightly late and very short and scanty. She had for twenty years been continuously under treatment of various sorts, including thyroid and pituitary preparations, without relief. In the past year her headaches had become practically continuous and she was utterly exhausted. A report of an x-ray study made in 1929 read "The sella turcica appears to be smaller than normal and the posterior clinoids are prominent." For part of the first month she was given a small dose of thyroid by mouth and gonadotropic factor from pregnancy urine by hypodermic injection with slight improvement. The second month she was given estrogen both by mouth and by hypodermic injection with moderate improvement. The third month, June 1933, she was given a full course of gonadotropic factor, and this treatment is still, in May 1936, being continued in reduced dosage. During the past three years her periods have been more normal in amount and without suffering. She has very rarely had a headache and never a severe one except during a period of time when treatment was discontinued for two months. Whereas she was previously an invalid, she has for the past three years been running the household for a large family.

CASE 5.—A married woman, aged 28, had severe menstrual cramps until her first pregnancy, which was terminated at three and one-half months by a therapeutic abortion because of pernicious vomiting. After this she had no cramps but instead each month a severe headache with nausea on the last day of her period. The duration of this complaint had been over a year, when in August 1933 she was given one course of gonadotropic factor from the urine of pregnancy. In February 1936 she reported that she had not had a headache since that time.

CASE 6.—A girl, aged 17, complained of a severe headache every month just before or after her periods, which began at 12½ years. During the past year the headaches had been much worse and appeared at other times of the menstrual cycle also. In October 1933 she was given one course of gonadotropic factor from pregnancy urine, following which she was entirely free from headaches except during one menstrual period, until last seen one and one-half years later.

CASE 7.—A nurse, aged 31, single, had been variously treated for headaches, often accompanied by nausea and vomiting, which always recurred two or three days before menstruation. In September 1933 she was given thyroid and one course of gonadotropic factor from the urine of pregnancy, which was followed by three symptom-free periods. The next month, while she was still taking thyroid, the headache recurred, though it was not so severe as originally. Following a second short course of gonadotropic therapy her periods remained symptom free and regular until July 4, 1935, when eighteen days after the onset of the previous period uterine bleeding began, which lasted for twenty-eight days and ceased after she received daily doses of from 1 to 2 cc. (125 to 250 rat units) of gonadotropic factor from pregnancy urine. It is of interest that after each of the first few of these large doses headache developed, the first headache of any sort she had had for nearly two years. X-ray studies of the patient's sella turcica show a complete bony bridging between the anterior and posterior clinoids.

#### COMMENT

Further detailed histories would be wearisome, but seventeen patients with menstrual migraine have been similarly treated and followed over a period of three years. All were relieved although some, usually those who had suffered most severely over the longer periods of time, have been unable to discontinue treatment entirely. This does not mean that all patients with such headaches would be relieved or even so treated. Many respond favorably to other methods of treatment, notably either the estrogen or estriol complex (emmenin). Others have suffered local and general reactions so that treatment was discontinued, as in the following case: A woman, aged 25, amenorrheic for two years, had migraine attacks usually at intervals of from four to six weeks. Repeated attempts were made to treat her with gonadotropic substance from pregnancy urine diluted with ten times the usual amount of distilled water. Treatment was begun with as little as 0.2 rat unit, but usually when a dose between 2 and 4 units was reached she would have a severe reaction with fever as high as 103 F. It was subsequently found that an injection of an estrogenic preparation would quickly relieve her headaches, which eventually after four years of amenorrhea disappeared spontaneously. She also had a small, completely bridged sella, not included in the summary of x-ray studies which appears later.

Therapy with gonadotropic factor from pregnancy urine has also been tried in cases of migraine not associated with menstruation, without relief; in one case there was a decided aggravation of the attacks.

Of the seventeen women, eight had previously had estrogen therapy. Of these, four had been moderately benefited, three were unimproved and one complained that her headaches were much worse.

ing roentgen evidence. Roentgen or radium therapy has the same favorable effect on hemangioma of bone as on hemangioma of soft tissue if treatment is early before dense bone is deposited within the tumor. Even later it is of definite benefit in arresting growth. The sensitivity of benign hemangioma to roentgen therapy must not be interpreted as evidence favoring malignancy.

## LOCALIZATION OF VENTRICULAR EXTRASYSTOLES

IN A HUMAN HEART WITH RIGHT  
AXIS DEVIATION

MYRON PRINZMETAL, M.D.

LOS ANGELES

BERNARD S. OPPENHEIMER, M.D.  
AND

SIMON DACK, M.D.

NEW YORK

The localization of the origin of ventricular extrasystoles and of the lesion in bundle branch block is still subject to dispute. Three separate ideas prevail:

1. The classic interpretation based on the fundamental studies of Lewis<sup>1</sup> and of Rothberger and Winterberg<sup>2</sup> is that the main ventricular deflection in left ventricular extrasystoles and in right bundle branch block is upright in lead 1 and inverted in lead 3. Right ventricular extrasystoles and left bundle branch block have an opposite configuration. This conception is based on experimental work performed on dogs.

2. The new terminology based on the observations of Barker, MacLeod and Alexander,<sup>3</sup> Oppenheimer and his collaborators<sup>4</sup> and Wilson<sup>5</sup> is exactly the opposite of the classic interpretation. This conception has been accepted by most but not by all authorities in this field.

3. Finally there is the opinion of Katz<sup>6</sup> that localization of extrasystoles and bundle branch block is impossible in man.

The recent observations of Kountz and his co-workers<sup>7</sup> are of interest. Human hearts were revived immediately after death and studied in regard to localization of ventricular extrasystoles and bundle branch block.<sup>7a</sup> In all eight instances in which the

human heart was stimulated the experimentally produced extrasystoles were similar in configuration to those found by Barker, MacLeod and Alexander.<sup>3</sup> The right and left bundle branches were cut in five instances and the results confirmed the observations of Oppenheimer and his co-workers<sup>4</sup> that the common type of bundle branch block is due to a lesion of the left bundle branch, while the unusual type is due to lesions of the right branch. Their studies seem to be a complete confirmation of the new terminology of the electrocardiogram. It was later found<sup>7b</sup> that when a dog's beating heart was placed in the human pericardial cavity so that a normal or left axis deviation resulted, the electrocardiograms of experimentally produced extrasystoles and bundle branch block were similar to those found in the human hearts. However, if the dog's heart was rotated so that a right axis deviation resulted, the configuration of the electrocardiograms of the extrasystoles and bundle branch block corresponded to the classic interpretation and was opposite to that found in the presence of left axis deviation. Recently Abramson and Weinstein<sup>8</sup> showed in cats that the direction of the major ventricular deflection in lead 1 changes at a line of transition which does not strictly divide the left from the right ventricle. A shift in this line of transition on the heart occurred with rotation of the heart and

change in electrical axis. Because of these observations it was felt important to study experimentally produced ventricular extrasystoles in the living heart with a right axis deviation. Recently we have had such an opportunity and the results of these observations form the basis of this report:

Fig. 1.—Electrocardiogram before operation, showing right axis deviation.

A laborer, aged 38, entered the Mount Sinai Hospital complaining of ascites of about eighteen months' duration. His present illness began one and

a half years before admission, at which time he noticed tenderness of the abdomen, vague pains in the epigastrium and swelling of the ankles. Fluid soon began to accumulate in the right pleural cavity. Mercurial diuretics and repeated tapping of the chest and abdomen were resorted to.

On physical examination on admission the patient was pale, thin and slightly cyanotic but not dyspneic or orthopneic. The veins of the neck were distended and were observed to fill during inspiration. The heart was of normal size and shape and the sounds were of good quality. There was no shift of the heart in any position. No systolic retraction was seen. The blood pressure was 105 systolic, 85 diastolic. No pulsus paradoxus was present. The liver was enlarged 5 cm. below the costal margin and ascites and dependent edema were present. The electrocardiogram (fig. 1) showed a regular sinus rhythm and a right axis deviation. The T wave was iso-electric in lead 1 and inverted in leads 2 and 3. In the right lateral position a slight shift in axis deviation occurred, but none occurred in the left lateral position.

## SUMMARY

1. The result of treatment with gonadotropic factor extracted from the urine of pregnancy in seventeen cases of menstrual migraine followed over a period of three years was relief in all. These were selected cases, all with a special type of migraine.

2. In only four of the eleven cases studied roentgenologically was a normal sella turcica found.

3. To explain the results, the following hypothesis is submitted: These seventeen women were all menstruating more or less regularly and therefore could not have had a severe form of pituitary deficiency. Consequently administering gonadotropic substance from pregnancy urine to them was equivalent to the combined therapy of this factor and the "synergist" from the anterior pituitary, which combination has been shown to produce maximum ovarian stimulation.

4. The results tend to confirm the hypothesis that a leading factor in the production of menstrual migraine is an ovarian hypofunction, perhaps associated with an anterior pituitary hyperfunction.

1421 State Street.

## A QUANTITATIVE STUDY OF THE FRIEDMAN TEST FOR PREGNANCY

G. LOMBARD KELLY, M.D.

AND

E. BRYANT WOODS, M.D.

AUGUSTA, GA.

What constitutes a positive reaction of the ovaries of the rabbit in the Friedman<sup>1</sup> modification of the Aschheim-Zondek test for pregnancy? Of what age and weight must the test animals be? What effect does the specific gravity and the reaction of the urine have on the outcome of the test? May the ovaries be examined always by the naked eye with the assurance of correct interpretation? Which is superior in accuracy, the original or the modified Friedman technic? How much blood serum must be used instead of urine when indicated and how accurate is the result? These and other questions occur to those using this important diagnostic procedure and, while numerous articles have been published about the Friedman test, the answers are not all available from one source.

In this study between 175 and 200 doe rabbits were employed. A few of these died before routine ether extraction of urine was begun. Urine specimens were obtained through the outside obstetric service from patients known to be pregnant. Blood serum was also obtained from such patients. The following data were recorded in each test: the animal's weight, color and breed, the patient's clinic number, which pregnancy and number of months, the specific gravity and reaction of urine, the exact technic, and the number of clear, ruptured and unruptured hemorrhagic follicles. In every case the ovaries were examined by the senior author with the aid of a low power binocular microscope (magnification about 12 diameters).

In extracting with ether, about 2 ounces (60 cc.) of the urine is placed in a separatory funnel with an equal quantity of ether and shaken thoroughly, after which

the urine is drawn off. This should be done as a routine unless the specimen is known to be quite fresh. Extraction is especially desirable when the specimen has been shipped from a distance with tricresol or saponated solution of cresol as a preservative (2 drops to the ounce).

In examining the ovaries with the low power binocular one must look for the crater of the follicle where the ovum escaped. It is worth while to insert the tip of a teasing needle into the crater and to manipulate the albuminous material that clings to the crater and lies on one side of the ruptured follicle. It is also important to remember that ruptured follicles may not be hemorrhagic but at times are quite pale. In many instances ovaries would be read as negative without such careful examination. The discovery of only one ruptured follicle in only one ovary must be considered as a distinctly positive reaction.

The efficiency of the Aschheim-Zondek pregnancy test as well as of the Friedman modification has been so well established that in this study no attempt has been made to appraise its value. Consequently no mention is made of negative tests when of no significance in the quantitative investigation.

The urine or blood serum was injected into the marginal ear vein in the usual manner and the animals were killed in the majority of cases by injection of from 5 to 10 cc. of air into the vein, though a few were killed by trauma.

## RESULTS

1. *Number of Ruptured and Unruptured Follicles.*—(a) There were seventy-five positive tests with the common modification of the Friedman test of administering 10 cc. of urine twice with a twenty-four hour interval and killing the animal forty-eight hours after the first injection. In fifty-three instances the ovaries presented both ruptured and unruptured follicles; in twenty-two cases there were no ruptured follicles though unruptured follicles were present; in only one case was there no unruptured follicle when ruptured follicles were found. In the entire series the average number of ruptured follicles per test (both ovaries) was 1.55; the average number of unruptured follicles per test (both ovaries) was 6.18. The percentage of animals with ruptured follicles was 70.67. In no instance was a corpus luteum visible to the naked eye. Corpora haemorrhagica are not transformed into corpora lutea (visible to the naked eye) in the ovary of the rabbit within forty-eight hours after copulation or the injection of urine from pregnant women.

(b) When the original Friedman method of injection was used (4 cc. three times a day for two days, killing the animal forty-eight hours after the first injection) the results were positive in twenty-seven instances. In nineteen cases the ovaries were found to have both ruptured and unruptured follicles; in eight cases there were no ruptured follicles, though unruptured follicles were present; in no instance were unruptured follicles absent. The average number of ruptured follicles was 1.7 and the average number of unruptured follicles was 8.7.

The percentage of cases in this series that showed ruptured follicles is almost identical with the percentage in series a: 70.37 per cent compared with 70.67 per cent.

(c) In a series of nine cases the test was positive when the doe was killed thirty-six hours after one injection of 10 cc. of urine. In six cases there were both ruptured and unruptured follicles; in three cases there were no ruptured follicles, though unruptured

In the remaining eleven cases<sup>11</sup> in which the human heart was directly stimulated and in which a normal or left axis deviation was present, the results were uniform and support the newer terminology. It is thus concluded that the newer terminology should be retained only in the presence of a normal electric axis or of a left axis deviation.

From the observations reported here, it may follow that the lesion in bundle branch block in hearts which previously had right axis deviation may be on the side opposite to that postulated by the new terminology. A certain amount of clinical and experimental evidence is in harmony with such a point of view.

The electrocardiographic configuration of right bundle branch block, according to the new terminology, is much more common in patients with conditions that ordinarily are associated with right axis deviation, such

block develops it conforms to the usual type,<sup>12</sup> whereas if a right axis deviation has been present and bundle branch block develops, what is thought to be a right bundle branch block according to the newer terminology occurs.<sup>14</sup> Katz and his co-workers have shown that the configuration of bundle branch block in man<sup>16</sup> and in dogs<sup>17</sup> can be reversed by changing the position of the heart, a procedure which alters axis deviation.<sup>18</sup> When the heart of a dog with experimentally produced right bundle branch block was rotated so that the right ventricle was anterior, a complete reversal in the form of the bundle branch block occurred. This procedure has been shown to cause a right axis deviation.<sup>18</sup> In mitral stenosis the heart is frequently rotated in this direction because of the large right ventricle.

#### CONCLUSIONS

1. Left ventricular extrasystoles were experimentally produced during a surgical operation by direct electrical stimulation of the upper part of the left ventricle about 3 cm. lateral to the septum, in a patient whose electrocardiogram showed right axis deviation. Following the operation right ventricular extrasystoles were mechanically induced by tapping four points on the chest wall overlying the right ventricle.

2. The major ventricular deflection of the extrasystoles induced from certain sites on the left ventricle was upright in lead 1. The major deflection of the extrasystoles arising from the right ventricle was inverted in lead 1 at three of the four points stimulated.

3. These observations do not conform to the newer terminology now widely used in the interpretation of the electrocardiogram. They lead us to believe that the newer terminology can be safely applied only in the presence of a normal electrical axis or of left axis deviation.

**The Tuberculin Reaction.**—After a period of from three to seven weeks of tubercle formation enough tuberculo-protein has been liberated by the bacilli, through disintegration and other processes, to result in sensitization of the tissues to this substance. Up to this time there has been no way of determining the presence of tubercle bacilli and tubercle formation in the body. There are no symptoms or abnormal physical signs, the tuberculin test is negative and roentgenograms give no aid. Indeed, before sensitization appears, tubercle formation is sufficiently under way to control the tubercle bacilli at least temporarily and often for the lifetime of the patient. After sensitization is established a most valuable diagnostic aid is available in that tuberculin or pure tuberculo-protein applied to an abrasion of the skin or administered intracutaneously results in a reaction which reveals the presence of sensitization to tuberculo-protein. As far as is known there is nothing which is taken into the body which results in such sensitization except tubercle bacilli which have caused tubercle formation. Thus, a positive reaction to tuberculin is highly diagnostic of the first infection type of tuberculosis somewhere in the body.—Myers, J. A.; Diehl, H. S.; Boynton, Ruth E., and Trach. Benedict: Development of Tuberculosis in Adult Life, Arch. Int. Med. 59: 1 (Jan.) 1937.

low power binocular microscope. Only high magnification of histologic sections could show them.)

2. In many cases the low power binocular microscope is necessary in order to reach a correct decision and will prevent repetition of the test in such cases. For recognizing ruptured follicles its use should be a routine.

3. The common modification of the Friedman test is satisfactory, though the original Friedman technic gives better quantitative results. One 10 cc. injection of urine with examination in thirty-six hours is not nearly so successful as the double injection, and better results would be obtained with two injections and examination in forty-eight hours.

4. Rabbits weighing more than 3 pounds will give better results than those weighing less, and 3 pounds is a safe minimum.

5. It is not necessary to acidify the urine, though it is better to do so, as the hormone present is more active in an acid medium. Urines do not kill test animals because of alkalinity.

6. It is safer not to use urines with a specific gravity of less than 1.008. If it is necessary to use such urines, the quantity injected in each instance should be increased at least 50 per cent.

## SUNRAY HEMANGIOMA OF BONE

WITH SPECIAL REFERENCE TO ROENTGEN  
SIGNS

WILLIAM E. ANSPACH, M.D.  
CHICAGO

Only twenty-one cases of hemangioma involving the skull have been found in the literature. Of 1,831 neoplasms of bone recorded at the bone registry, thirteen have been hemangiomas. Of these, only three have involved the skull. In Christensen's<sup>1</sup> collection of 918 neoplasms of bone, less than 1.5 per cent were hemangiomas. Geschickter and Copeland<sup>2</sup> report only twelve cases of hemangioma of all types of bones in a group of more than 1,700 neoplasms of bone. These authors call attention to the fact that most of the earlier reports failed to distinguish hemangioma from sarcoma. It is interesting, in this respect, that the case which I am about to report was thought to be sarcoma when first seen in 1921. The clinical course and roentgen appearance of hemangioma of the skull over a long period is of moment, as tumors of this character, as a rule, have been considered malignant and removed fairly early.

### REPORT OF CASE

F. S., a girl, aged 11 years, came to the Children's Memorial Hospital in 1921 because of a swelling on the left side of the scalp. This had first been noticed four years previously, following a slight bump on the head while playing. There was very little pain at that time and the swelling did not attract special attention until just before the patient came to the hospital. At this time a mass protruded from the left parietal bone for a distance of 3.5 cm. The patient was well developed and well nourished and appeared healthy in every way. The mass on the head was not tender and its surface was smooth to touch. There was no exophthalmos and the movements of the eyes were normal. The blood pressure was 118 systolic, 84 diastolic, the pulse 84, the temperature 98.6 F.

After one week's observation in the hospital, during which time roentgenograms of the skull (figs. 1 and 3) had been

secured and showed radiating spicules of bone within the tumor mass, it was thought that an osteogenic sarcoma most likely accounted for the tumor mass. Under ether anesthesia, removal was attempted by Dr. A. H. Montgomery. Trepine holes were made in the skull. These were followed by profuse bleeding, which could not be controlled with Horsley's wax. The bone was then cut between the trephine openings, following which the bleeding became so severe and so difficult to control that it was decided to discontinue the operation. The patient received 1,800 cc. of saline solution under the breast immediately while on the operating table, and one hour later 1,600 cc. intravenously. Two hours later she was given 150 cc. of citrated blood. Six hours later 10 cc. of horse serum was given into the buttocks. After ten hours the patient improved slightly, but the oozing of blood continued and the patient was given 2 cc. of hemostatic serum intravenously. Although slight bleeding continued for several days, the condition finally improved and the patient left the hospital at the end of five weeks. The parents were advised to have the patient return for roentgen therapy. This they failed to do.

The patient was lost track of until 1936, then 26 years of age. In the meanwhile, the x-ray films, presenting the "sunray" pattern, had been noted, and because of previous experience with "sunray" tumors involving flat bones, which had been proved to be hemangiomas, I thought that that condition most likely accounted for the x-ray appearance in this case and that the patient was still living. She was ultimately located and additional roentgenograms of the skull were made (figs. 2 and 4). The patient, now 26 years of age, is married and has a child 2 years old. She believes that the tumor has not grown in the past six years. The tumor is covered with normal soft tissue and has not interfered with the patient's health.

### COMMENT

The "sunburst" appearance on roentgenograms of tumors of bone have in the past played an important part in facilitating a preoperative diagnosis of osteogenic sarcoma. Many of the earlier reported cases in which the skull was involved were mistakenly called

Fig. 1.—F. S., aged 11 years, showing sunray hemangioma of the left parietal bone. Growth started four years previously, following a bump on the head.

sarcoma. Occasionally the histologic diagnosis was changed to hemangioma after the patient continued to live beyond the expected period. A typical example was given by Cushing<sup>3</sup> in 1923 of a patient still living three years after a postoperative histologic diagnosis of melanotic sarcoma. Cadman expressed doubts regard-

the abdomen revealed no gross abnormalities. The pelvic organs showed a cervical laceration. The knee jerks were hyperactive.

The basal metabolic rate was plus 6 October 31 and minus 6 November 12. X-ray examination revealed no evidence of substernal goiter. There was a slight enlargement of the cardiac shadow to the left. Blood count showed erythrocytes 4,400,000, leukocytes 7,400, hemoglobin 14.2 Gm., polymorphonuclears 63 per cent, lymphocytes 37 per cent. The urine was normal. Blood sugar was 100 mg. and blood urea 11 mg. per hundred cubic centimeters. The patient was considered to have a colloid goiter and was given desiccated thyroid gland 2 grains (0.13 Gm.) three times a day on the apparent evidence that the thyroid enlargement was in a sense due to work hypertrophy. November 22, after the patient had taken thyroid extract for three weeks, the basal metabolic rate had risen to plus 20. The desiccated thyroid was reduced to 1 grain (0.06 Gm.) three times a day, during which time abdominal pain developed in

Fig. 2.—Section under low power showing acini that are widely dilated and filled with colloid. In some of these there is proliferation, forming papillary projections into the acini.

the right lower quadrant. This was constant and associated with headache and pain in the right side of the neck at the site of the "goiter nodules." Twelve hours later cramps developed in the region of the umbilicus and the patient vomited. Toward late afternoon the cramplike pain extended to both lower quadrants of the abdomen but was more marked on the right side. There was also some tenderness and rigidity over the lower part of the abdomen. Peristalsis was hyperactive. The basal metabolic reading December 10 (at the time of abdominal symptoms) was plus 57. The blood count on the day when the pain was most severe was leukocytes 20,200, polymorphonuclears 67 per cent, lymphocytes 33 per cent. A surgical consultation with Dr. Eliason at this time suggested acute appendicitis. The patient was treated conservatively because of her extreme nervousness and her high basal rate. Hypodermoclysis was given. Twenty-four hours later abdominal pain ceased. There was some tenderness and rigidity over the lower right quadrant of the abdomen. The blood count showed white blood cells 29,000, polymorphonuclears 75 per cent, lymphocytes 25 per cent. At this time a persistent diarrhea

developed and the patient became quite restless. Dr. Eliason again saw her and suggested the probability of an appendiceal abscess and advised surgical intervention.

The appendix was removed and found on microscopic examination to be essentially normal, except for a slight activity of the lymphoid follicles and slight infiltration of the submucosa by small round cells. The patient became quite toxic and mentally disturbed. In view of the fact that there was neither any abdominal nor other inflammatory process found to account for her acute illness, and in view of a previous history of administration of thyroid extract, the last basal metabolic reading being plus 57, it was felt that the entire symptom complex was due to a thyrotoxicosis. In view of this she was placed on compound solution of iodine 15 minims (1 cc.) three times a day and saline hypodermoclysis. Seven days later the patient's general conditions had improved, the toxicity had decreased and the patient was returned to the medical ward in preparation for final thyroidectomy. Jan. 23, 1930, after three weeks on compound solution of iodine, the basal metabolic reading had decreased to minus 5. Six days later a subtotal thyroidectomy was done. After a stormy convalescence, during which the pulse rate went up to 180, she recovered completely and was discharged, January 28, from the surgical ward with a pulse rate of 88 and a basal metabolic rate of minus 11.

Histologic examination of the thyroid tissue reported on by Dr. W. P. Belk revealed the following: Sections gave rather an unusual picture. Certain areas showed widely dilated acini filled with colloid which had the normal acidophilic properties found in simple colloid goiter. In some of these there was proliferation, forming frondlike papillary projections into the acini. In other areas were numerous small closely packed acini, the lining of some of which was made up of rather tall columnar cells instead of the normal flat or cuboidal type, these areas being indicative of toxicity. Still other areas give the impression of having been stimulated to toxic proliferation with subsequent regression, an occurrence which sometimes results from administration of thyroid extract to patients with colloid adenoma.

The diagnosis was regressing toxic adenoma.

The patient was given thyroid extract with the hope of reducing the colloid tumor. The administration of desiccated thyroid resulted in acute thyrotoxicosis, the basal metabolic rate having risen to plus 57 from minus 6. During the thyrotoxicosis acute abdominal symptoms developed that resembled acute appendicitis. The appendix proved histologically to be normal. Subtotal thyroidectomy resulted in amelioration of the patient's thyrotoxic symptoms.

One of us knows of a patient who was admitted to the Mount Sinai Hospital of Philadelphia in the summer of 1933 with persistent vomiting, obstipation of nine days' duration and abdominal pain. The diagnosis of intestinal obstruction was made. A barium sulfate enema revealed marked spasticity of the rectum and sigmoid but no obstruction. After the acute emergency was over a more careful medical survey showed clinical signs of hyperthyroidism with a basal metabolic rate of plus 57.<sup>8</sup> A differential diagnosis cannot always be made. The patient's condition before operation suggests a widespread abdominal pathologic process.

CASE 2.—*Thyrotoxicosis with abdominal symptoms simulating appendicitis. Administration of compound solution of iodine relieved symptoms of thyrotoxicosis and abdominal pain. With omission of iodine therapy the abdominal pain recurred.*

Miss H. S., aged 17, came to Temple University Hospital Oct. 17, 1931, with palpitation, pain in the loin and a gain in weight (23 pounds [10.4 Kg.] in the past few months). The patient stated that she had been well until nine months before, when she commenced to put on weight. Gradually she became drowsy and less active. She ate moderately but drank large quantities of water. Menstruation began at the age of 14 and

8. Scarf, M.: Personal communication to the author, paper to be published in the Journal of Laboratory and Clinical Medicine.

and there has been too much destruction of preexisting bone for the perfect "sunburst" effect noted in the benign, slowly growing hemangioma. The fact that sarcoma of the long bones has been more often encountered no doubt accounts for the frequently mistaken diagnosis when the sunray hemangioma of flat bones has been present. Hemangioma of long bones only seldom has produced the more imperfect "sunburst" of sarcoma. As a rule its structure has been more complete, resembling more an osteochondroma or an overgrown cystlike structure, often suggesting its benign character. The cortex of involved bone is not broken into bits but is replaced by the hemangioma in a slow, most orderly fashion.

An almost constant x-ray appearance has been produced, according to numerous recent reports,<sup>5</sup> when hemangiomas involve vertebral bodies. Vertical streaks of parallel densities are seen on the roentgenograms somewhat resembling corduroy cloth. Older persons are especially prone to have this type of tumor. Only

Fig. 5 (case reported by T. D. Overend).—Hemangioma of occipital bone, showing the typical radiating spicules which arise from the space between the skull tables, as in the case here reported. (Hemangioma of Occipital Bone, Brit. J. Radiol. 6: 626 [Oct.] 1933.)

rarely do the early vertical striations change to a "blown-out" appearance or to a "mushrooming" of the vertebra. No other benign tumor has so uniformly produced these parallel densities.

The tendency for hemangioma of bone to produce a somewhat characteristic picture on roentgenograms seems to be due in part to the type of bone involved. Hemangioma of bone should be considered a possibility in all "sunburst" tumors of bones, but a malignant neoplasm should be considered equally probable when there is a sunray pattern on roentgenograms of long bones, especially if there has been active destruction of bone. Sharply defined, well organized trabeculae or spicules favor hemangioma. No tumor of this sort should be removed without a biopsy first, with the surgeon and pathologist both thinking of a benign hemangioma as a possibility.

Although gross evidence in many surgically removed hemangiomas of bone favors primary involvement of bone, opinions of pathologists seem to favor secondary

involvement. Secondary involvement of bone by large, soft tissue hemangiomas are apt to erode bone, leaving a smooth edged defect, as in other tumors (fig. 4). Growth is apt to occur rapidly, and there is no spicule formation.

#### SUMMARY

The roentgenographic changes of hemangioma of the skull in a child aged 11 years, first observed in 1921 and again fifteen years later, were studied. Excepting for

Fig. 6.—W. M., aged 6 years. Anteroposterior view showing a circular area of decreased density of the frontal bone. There is loss of the inner table due to erosion by contact from the tumor (meningioma) within the skull. This appearance should not be confused with hemangioma showing growth from cancellous space. Soft tissue hemangioma and primary brain tumors as well as meningioma have been known to produce this type of bone erosion.

a large mass on the head, the patient's health has not been impaired in any way. Hemangioma of flat bones produces a beautiful sunray formation on roentgenograms. Hemangioma of long bones often produces a "loose soap bubble"

appearance but almost as frequently the sunray pattern of density. The latter is often confused with osteogenic sarcoma of bone, which also produces divergent spicules of bone. While hemangioma is less destructive, slower growing and less painful and produces the more clearly outlined trabeculation, a biopsy should be

Fig. 7.—Lateral view of same case as shown in figure 6.

obtained before removal is attempted. Rarely should hemangioma of bone be removed. When hemangioma involves vertebrae, a vertical striated appearance is produced which is almost characteristic of this one type of tumor. Therefore the kind of bone involved by the tumor in a given case is of prime importance in weigh-

5. Bailey, Percival, and Bucy, P. C.: Cavernous Hemangioma of the Vertebrae, J. A. M. A. 92:1748 (May 25) 1929. Ireland, J.: Hemangioma of a Vertebra, Am. J. Roentgenol. 28: 372-378 (Sept.) 1932

One week after her discharge from the hospital she was readmitted with a loss of a few pounds, and the basal metabolic rate the following day was plus 39. The patient was placed on compound solution of iodine 10 minims three times a day, rest, sedatives and forced liquids. In the course of three weeks the basal metabolic rate again declined to plus 22, and although the pulse rate was elevated the patient was considered to be in a suitable condition for thyroidectomy. The latter was done Jan. 22, 1935. The day following the operation the pulse rate rose to 170, the temperature to 104 F., and stridor developed as a result of the edema of the glottis. In spite of tracheotomy she died twenty-four hours after operation. The microscopic examination of the thyroid by Dr. Custer was as follows: The majority of the acini were of normal size with slightly less than the usual concentration of colloid. The lining epithelium had reverted to the cuboidal type almost exclusively but still showed stratification in some acini; the epithelium was rather markedly degenerated in general as a result of iodine therapy. Lymphocytosis was not prominent. There was no evidence of neoplastic change.

The pathologic diagnosis was hyperplastic toxic goiter with iodine regression.

Autopsy by Dr. Morton McCutcheon, January 24, revealed the following gross anatomic diagnosis: slight edema of the larynx, heart normal except for enlargement of pulmonary conus. The lungs, spleen, liver and kidneys were normal. The right ovary was the seat of a unilocular cyst. There was chronic salpingitis of the tubes.

The histologic diagnosis was acute laryngitis, liver normal, ovarian cyst with hemorrhage, chronic salpingitis.

The cause of death was edema of the larynx following thyroidectomy.

The occurrence of syphilis in this patient, it would appear, was coincidental with the presence of hyperthyroidism rather than causative of thyroid overactivity. The antisiphilitic treatment failed to produce any great improvement, but delay of the appropriate treatment aggravated the patient's condition. The failure to respond to antisiphilitic treatment is an important factor against the assumption that the patient suffered from a syphilitic hyperthyroidism as described by Lévy-Franckel.<sup>9</sup> Then again the histologic examination of the thyroid gland showed no evidence of a syphilitic involvement.

The enlargement of the spleen as elicited clinically is not an unusual finding in hyperthyroidism. It is to be looked on as a part of the general picture of the status thymicolymphaticus described by Chvostek Jr.<sup>10</sup> and Warthin.<sup>11</sup> At the postmortem examination the spleen weighed 140 Gm., which is moderately large for the spleen of a Negro.

It is interesting to note that the abdominal pain disappeared when the thyrotoxic symptoms decreased, and it reappeared with a recurrence of signs of hyperthyroidism. That the abdominal pain was not due to a tabetic crisis is evident from the fact that the patient had no neurologic signs of cerebrospinal involvement and that the pain was not of the character seen in *tabes dorsalis*.

#### SUMMARY

It should be appreciated that hyperthyroidism may play an important part in the production of signs and symptoms referable to the abdomen. They may be so severe as to suggest a surgical catastrophe. In two of three such cases the abdominal signs mimicked acute appendicitis. One of these patients was operated on and a normal appendix was found by the surgeon. The pains in the third patient were localized in the left

upper quadrant of the abdomen. Postmortem examination showed no abdominal pathologic condition to account for the pains.

Differentiation is not always possible, since hyperthyroid patients may harbor lesions of the gastrointestinal tract. When appropriate therapy is applied, the abdominal symptoms disappear with other signs of hyperthyroidism. In the surgical cases the signs and symptoms usually progress.

## TREATMENT OF ORGANIC ARTERIAL OBSTRUCTION BY ALTERNATING SUCTION AND PRESSURE

A DEVICE TO RELIEVE INCIDENTAL ARTERIOSPASM

EDWARD ALLEN EDWARDS, M.D.

BOSTON

Suction pressure therapy, in common with most forms of treatment of organic arterial obstruction, has as its aim the dilatation of the smaller arteries and arterioles, thus promoting a circulation collateral to the obstructed large arteries. There seems to be no reason to believe that such therapy can have any effect on spasm of these vessels. Nevertheless, such spasm is present in many cases of organic disease and adds materially to the obstruction caused by the organic lesion. Moreover, this spasm actually tends to keep contracted the very vessels that the treatment hopes to dilate and is therefore antagonistic to the treatment.

This spasm is prominent in the acute obstructions, especially embolism and thrombosis. Indeed, experience shows that when embolism occurs in a peripheral artery, if only the factor of spasm is removed, the collateral circulation may spontaneously become adequate to avert gangrene. In the case of thrombosis, one is dealing not with a separate disease entity but usually with a condition which occurs at some time or other in the course of almost every case of chronic arterial disease. With the access of this condition, arteriospasm supervenes on the organic obstruction and may continue for weeks or months.

In considering spasm in the chronic diseases, I shall but briefly mention arteriosclerosis, as this disease is almost free of arteriospasm, except at the infrequent times when thrombosis occurs. Thrombo-angiitis obliterans, on the other hand, is frequently complicated by a great deal of arteriospasm. This is probably due to the fact first that, unlike arteriosclerosis, it entails an inflammation of the vessels from its very start, and secondly that thrombosis is frequent and extensive.

There is also a tendency to contraction of the arterioles and capillaries of the treated limb as the result of physical changes in the suction pressure treatment proper. This is due to cooling of the skin first by the creation of a partial vacuum and secondly by the increase in evaporation of the perspiration, caused by air currents in the treatment cylinder, or "boot." The first item is not great. The temperature of the air in the cylinder as measured by the electric thermocouple falls from 0.5 to 0.7 C. during the suction phase and rises from 0.1 to 0.3 C. during the pressure phase. This fluctuation is greater when the air is at room

A diagnosis of chronic constrictive pericarditis (concretio cordis) was made and partial pericardiectomy was performed on two occasions by Dr. Harold Neuhof. At the first operation the heart was exposed through an anterior mediastinal incision, after removal of the second to sixth left costal cartilages and adjacent portions of ribs and part of the sternum. The entire heart was found encased in a white, fibrous, immobile membrane about 0.5 cm. thick. The fibrous tissue was dissected away down to the epicardium from the apical region of the left ventricle and anterolateral surface of the right ventricle. The total area of removed pericardium measured about 8 cm. in diameter. An effort was now made to stimulate the right

axis deviation during this procedure is not as marked as in the other tracings, owing to the rotated position of the patient.

2. Right ventricular extrasystoles: Mechanical stimulation of the right ventricle gave the following results (fig. 3): In three locations, points A, B and C, the main ventricular deflection was inverted in lead I and upright in lead 3. The main deflection of the extrasystoles resulting from stimulation of point D was upright in lead I and inverted in lead 3.

#### COMMENT

These observations demonstrate that the configuration of ventricular extrasystoles in the presence of right axis deviation does not conform to the newer interpretation, which postulates that the major ventricular deflection in lead I is always inverted in left ventricular extrasystoles and upright in right ventricular extrasystoles. An analysis of the literature reveals that there are two other cases in which extrasystoles were experimentally produced in the presence of a right axis deviation, and in both of these instances, as in the present one, the resulting electrocardiograms did not conform to the criteria of the new terminology. In the case reported by Lundy and Bacon<sup>9</sup> in which the heart was directly stimulated, extrasystoles arising from the apex of the left ventricle conformed to the new terminology. Extrasystoles induced by them by stimulating the basal part of the left ventricle were similar to those obtained in the present study on stimulating approximately the same area; in both the major deflection was upright in lead I. In the report of Oppenheimer and Stewart,<sup>10</sup> in which a right axis deviation was also present, the

Fig. 2.—Extrasystoles produced experimentally by stimulation of the upper lateral region of the left ventricle.

ventricle, but no extrasystoles were induced because of insufficient stimulating current (15 volts).

Since there was very little improvement following this procedure, a second operation was performed. The heart was now approached through a left lateral transpleural incision and the thick pericardium removed from the anterolateral surface of the left ventricle for an area of from 6 to 8 cm. in diameter. The heart's action improved distinctly, and the pulsations, which were scarcely visible at the beginning of the operation, were now pronounced and strong. The systolic blood pressure, which was previously 105 mm., rose 20 mm. at this stage of the procedure.

An attempt was made to stimulate the left ventricle, which was now completely exposed over a wide area. The stimulating electrode was similar to the one devised by Barker, MacLeod and Alexander.<sup>3</sup> A current of 20 volts repeated sixty times a minute was first used. Since no extrasystoles occurred, the voltage was gradually increased to 45 volts. The upper part of the left ventricle in a region about 3 cm. to the left of the septum was stimulated. This area was somewhat more lateral to points designated 1 and 2 by Barker, MacLeod and Alexander. Extrasystoles occurred immediately following the stronger electrical stimulus. Leads 1 and 3 were recorded simultaneously with a two-string galvanometer. For a control period of five minutes with lesser voltage and another period of five minutes immediately after the operation, no extrasystoles were found. Nor were spontaneous extrasystoles ever present in eleven routine electrocardiograms taken before and after the operations.

Following the second operation a marked clinical improvement occurred and the signs of obstruction of venous return to the heart disappeared. The latter was now covered only by a thin layer of skin and subcutaneous tissue, and a well marked precordial pulsation could be seen and felt. It had been observed during both operations that the surface of the heart in contact with the chest wall between the sternum and the left nipple consisted mainly of the right ventricle. It was now found that extrasystoles could easily be induced by tapping the thin chest wall overlying the right ventricle. Four points within the nipple line were arbitrarily chosen (fig. 4). This procedure was carried out on four separate occasions.

#### RESULTS

1. Left ventricular extrasystoles: The electrocardiograms resulting from the extrasystoles induced by electrical stimulation of the left ventricle are shown in figure 2. Eleven ventricular extrasystoles, all of similar configuration, occurred in the two minute period during stimulation with 45 volts. It may be seen that the main deflection is slightly but definitely upright in lead I (approximately 2 millivolts in height) and also upright in lead 3 (approximately 10 millivolts in height). The right

Fig. 3.—Extrasystoles produced by tapping points A, B, C and D on the anterior chest wall overlying the right ventricle.

extrasystoles corresponded to the classic interpretation and were distinctly opposite to that of the newer terminology. In their case the heart was not exposed but was stimulated through the skin, and so some uncertainty existed as to the exact location stimulated.

increase in metabolism caused by local heat is of distinct benefit in increasing the processes of slough and repair. He reports favorable results in the healing of ulceration and in the demarcating of gangrene by using the preheated air during the treatment.

With these considerations in mind, I have been using a device for warming the limb during treatment in the suction pressure apparatus shown in the accompanying illustration. The device consists of two 75 watt tubular warmers, each suspended in the center of a wire guard. Thus protected, each warmer is bolted on either side of the interior of the treatment chamber. The current to the warmers is regulated by a bimetallic thermostat of conventional design, to give a controlled temperature range from 90 to 110 F. (32.2 to 43.3 C.). For use with direct current a condenser of 1 microfarad is further connected to the thermostat to cut down arcing at the contact points.

The use of this controlled local warmth of the treated limb seems to bear out the theoretical considerations, since with it the suction pressure treatment seems to be more effective.<sup>12</sup> This is true even in cases of arteriosclerosis in which no appreciable spasm is present. Here one must consider, I believe, that above the level of maximum ischemia there are still dilatable vessels; that is, in the region of the knee and thigh.<sup>13</sup> It is in order that these vessels may be influenced by the suction and the warmth that one should insist on inserting the limb far enough into the cylinder so that the cuff lies well up on the thigh.

Freeman has pointed out that pain is one of the best indications that heat around a limb is excessive; that is, that the metabolic increase caused by the heat is in excess of the increase in blood flow. Thus the temperature chosen for any patient is that which the patient finds most comfortable and is never above 110 F. Such relatively high temperatures are comfortably endured because the suction is able to increase the blood flow beyond the increased demands of the metabolism. There are some patients whose smaller vessels are so badly obstructed that the suction results only in a very slight increase in the circulation. The same is true of some sudden obstructions, as by thrombosis. In such instances it is safest to keep to very low temperatures, about 90 F., and, if the temperature cannot be increased without causing pain, to seek further vasodilatation by means of drugs or nerve block.

#### SUMMARY

In cases of both acute and chronic organic arterial obstruction there is apt to be an associated spasm of the collateral vessels. This spasm counteracts the effect of the suction-pressure therapy and is not relieved by the treatment.

A device is here described to furnish warmth to the affected extremity while it is treated by suction-pressure. Such locally applied warmth is capable of maximum vasodilatation and increases the effectiveness of the suction. Moreover, the local increase in metabolism caused by the raised temperature assists in the processes of healing.

330 Dartmouth Street.

12. Theis and Freeland (J. A. M. A. 107: 1097 [Oct. 3] 1936) have concluded that warming the upper limbs during the suction pressure treatment gives better results than when the suction pressure treatment is used without such warming. They have additionally concluded that this combination is better than heating the lower limbs directly during the treatment. The latter point seems inconclusive, so far as their published work goes; and it is at variance with the experimental work quoted by me.

## THE CAUSE OF JOINT PAIN

OCCURRING DURING ACTIVE IMMUNIZATION WITH  
SCARLET FEVER STREPTOCOCCUS TOXIN

CLAIRE E. HEALEY, M.D.

CHICAGO

It has been observed that, during the course of immunization of young adults against scarlet fever, approximately 3 per cent complain of joint pains following one or more doses. These pains are sometimes associated with swelling of the joints involved. They usually develop within twelve hours following a dose of scarlet fever streptococcus toxin and last from a few hours to several days, when they disappear, leaving no residual effect. The question arises Do these pains occur as a direct result of the action of the streptococcus toxin on the joint tissue or do they occur because the involved joint tissue has at some time become sensitized to the protein contained in the toxin solution? In the latter case has the protein concerned resulted from the growth of the streptococcus or is it protein present in the broth used for production of the toxin? The following experiments were undertaken in an attempt to clarify these questions:

#### FIRST EXPERIMENT

To five young adults who complained of joint pains during the course of immunization against scarlet fever, sterile veal broth culture medium was given. This broth was from the identical lot that was employed in the

TABLE 1.—Joint Pains Occurring on Two or More Occasions  
Following Administration of Scarlet Fever Toxin;  
No Joint Pains Following Administration  
of Veal Broth Medium

causing joint pains	1
Scarlet fever as a child with no arthritis	1
Frequent sinusitis before removal	1
Growing pains and occasional sore	1

production of the toxin being used in the immunization. One week after the administration of the dose of toxin that produced the joint pains, a dilution of the broth was given containing the same concentration of medium that was present in the next larger dose of toxin. The following week the corresponding dose of immunizing toxin was given. The reaction was noted after each dose and the procedure was repeated each time the patient reported joint pains. No information was given the patient concerning the content of the doses. A history was obtained pertaining to the previous occurrence during their lives of joint pains, "arthritis," "rheumatism," growing pains when a child, chorea and cardiac symptoms as well as frequency and severity of sore throat and tonsillitis.

Table 1 indicates five persons who had joint pains at least twice following the administration of scarlet fever streptococcus toxin with no joint pain on the subsequent administration of veal broth medium diluted to contain the concentration of broth protein to be found in the next larger dose of toxin. In one of these persons the arthralgia started with the second dose and continued through the fifth dose of toxin, alternating regularly with no joint pain when the subsequent dose of veal broth medium was given.

## HYPERTHYROIDISM MASKED BY SYMPTOMS OF ACUTE ABDOMINAL CATASTROPHE

WILLIAM E. ROBERTSON, M.D.

MICHAEL G. WOHL, M.D.

AND

HAROLD F. ROBERTSON, M.D.

PHILADELPHIA

Cases of acute abdominal pain occurring during the course of thyrotoxicosis have been reported in the continental literature by Stern,<sup>1</sup> Kraus<sup>2</sup> and Desbouis.<sup>3</sup> The American literature contains scant reference to it. Horsley and Rosebro<sup>4</sup> reported a case of hyperthyroidism in which the chief complaints on admission to the hospital were indigestion, pain in the abdomen and bearing down in the pelvis. Operation revealed, however, a chronic adherent appendicitis and pathologic condition of the pelvis. Lahey<sup>5</sup> states that he has never seen a condition similar to the one dealt with in this presentation.

The practicing physician is well aware that abdominal pain suggestive of acute abdominal disease may merely express pain impulses from disease of the thoracic viscera. The "ruptured gastric ulcer and acute appendicitis" have not infrequently turned out to be a frank pneumonia, to the chagrin of the surgeon and the internist. The nausea, vomiting and pain in the right upper quadrant with the local spasm and tenderness of the rectus muscles so characteristic of an acute gallbladder attack have often mimicked coronary thrombosis or angina pectoris. The masquerading of such medical conditions as intra-abdominal disease is well known to the experienced physician. That metabolic disturbances will often mimic intra-abdominal lesions is not generally appreciated. Recently one of us<sup>6</sup> emphasized that the acidosis of diabetes mellitus requires differential consideration in abdominal catastrophes. In hyperthyroidism patients may likewise exhibit acute attacks of vomiting and abdominal pain which may be erroneously construed as arising from an acute intra-abdominal surgical lesion. Unless the examiner is familiar with this symptom complex and looks for other signs of hyperthyroidism, his attention will be riveted to an intra-abdominal organ or organs not responsible for the disease. The patient may thus be subjected to the grave risk of an unnecessary exploratory operation.

It is to be borne in mind that in patients with hyperthyroidism there is a rather high incidence of duodenal and gastric ulcers,<sup>7</sup> which may be the cause of acute abdominal symptoms in some patients.

This presentation, however, deals with instances in which the acute symptoms and signs referable to the abdomen are due entirely to the overactivity of the thyroid gland.<sup>7a</sup>

## REPORT OF CASES

CASE 1.—*Acute thyroid crisis masked by abdominal symptoms of acute appendicitis. Operation revealed a normal appendix.*

Miss M. B., a Negress, aged 19, admitted to the Philadelphia General Hospital, service of Dr. William E. Robertson, Oct. 18, 1929, complained of swelling of the neck and nervousness. The patient had been perfectly well until five years before admission. At that time her menstrual cycle began, and with this she first became aware of a small uniform enlargement at the base of the neck. It did not give rise to local discomfort, but nervousness developed at this time. Three years later, at the age of 17, she became pregnant. After delivery of a full term child she observed that the lump in her neck suddenly became larger; with the delivery of a second child one year later she noticed

Fig. 1.—Section under low power from the appendix, showing slight activity of lymphoid follicles and some round cell infiltration of the submucosa.

that the growth became nodular. At the time she experienced a heavy oppressive sensation over the neck, and with it she became quite nervous and irritable. Excessive perspiration and hypersensitiveness to heat developed. Three weeks prior to admission to the hospital the patient noted cardiac palpitation with oppression in her neck. There was no loss of weight, although there was ready fatigability in the last few months.

The immediate past history was irrelevant.

The patient was well nourished. She was not acutely ill but was emotionally unstable. The skin was moist. She had suffered several attacks of urticaria. There was widening of the palpebral fissures with slight exophthalmos, especially of the left eye. The tongue was tremulous and protruded in the midline. There was marked and total enlargement of the thyroid gland. Several nodules the size of marbles were palpable in both lateral lobes. In the isthmus there was a large nodule the size of a small egg. The heart was of normal size and the sounds were of good quality, the apical rate being 90. The blood pressure was 116 systolic, 90 diastolic. Examination of

in childhood and one with growing pains and possible symptoms of mild cardiac involvement. Growing pains were reported in six other patients in the group of twenty-three, occurring either alone or in combination with frequent sore throat, tonsillitis or cardiac difficulty. Seven more patients of the twenty-three reported sore throat or tonsillitis, in one instance associated with cardiac symptoms. Four patients in this group gave no history of the foregoing symptoms.

Group 3. Those patients who complained of joint pains after injection of unmodified toxin and who had less pain on injection of heated toxin.

Table 4 indicates the eleven persons in this group. They exhibited joint pain following a dose of unheated toxin, but joint pain was present also in a lesser degree on administration of heated toxin. Four of these patients had had previous joint pain, one twelve years previously following pneumonia and more recently following tonsillitis, one associated with growing pains, tonsillitis and sinusitis as a child, one associated with severe growing pains, tonsillitis, mastoiditis and a cardiac murmur, and one following scarlet fever at 6 years. Two of the eleven reported growing pains, one associated with chorea as a child, and one with frequent sore throat as a child. One patient gave a history of frequent sore throat before the removal of tonsils. Four in the group of eleven gave no history of the foregoing symptoms.

Group 4. Those patients who had irregular occurrence of joint pains after injection of heated as well as of unheated toxin.

Table 5 indicates these five persons. Their joint pains were irregular, occurring at times with greater severity following the administration of heated than of unheated toxin. Three of these patients had had previous joint pains, two associated with "influenza" and one with a streptococcic sore throat three months previously. One of these five patients had a streptococcic sore throat during the time she was receiving doses, and the remaining patient gave a history of frequent attacks of sore throat as a child and had had a severe generalized protein reaction with some of the doses. Heated toxin was not continued in this instance because of the severe discomfort of the patient.

#### SUMMARY

1. Joint pain was caused in sixty-three young adults by the subcutaneous injection of sterile, filtered streptococcus toxin in broth solution.
2. Of these sixty-three patients fifty-three, or 84.1 per cent, gave a history of previous occurrence of joint pain or of symptoms suggestive of rheumatic infection or previous streptococcic infection.
3. In forty-seven, or 74.6 per cent, the joint pain produced by the injection was due to the toxin alone.
4. In eleven, or 17.4 per cent, toxin was the chief factor in the causation of joint pain.
5. In five, or 7.9 per cent, the joint pains were not caused by the toxin but were attributable to protein contained in the broth solution or to coincident active foci of infection in these patients.

#### COMMENT

Subcutaneous injection of sterile filtered scarlet fever streptococcus toxin into the upper arm may produce a painful reaction in the joints of persons who give a previous history of joint pain or of symptoms suggestive of rheumatic infection or previous streptococcic infection. Infrequently painful joint reactions occur when such a previous history cannot be elicited.

The fact that in most instances pain caused by sterile filtered streptococcus toxin in broth solution could not be reproduced when the toxin in the solution was destroyed by heating or when diluted broth was given indicates that the pain was most frequently due to toxic action and not to sensitization to protein resulting from the growth of the streptococcus or to protein present in the broth used in the production of the toxin.

#### CONCLUSION

In persons who have previously suffered an infection involving the joints, acute temporary recurrence of the joint pains may be elicited by absorption of sterile streptococcus toxin produced in many instances by a type of organism probably not responsible for the primary infection.

629 South Wood Street.

### EFFICACY OF VARIOUS MEDICAMENTS IN THE TREATMENT OF VIN- CENT'S STOMATITIS

REPORT OF SEVEN HUNDRED AND NINETY-  
FOUR CASES

G. W. FARRELL, D.D.S.

AND

W. A. McNICHOLS, M.D.  
DIXON, ILL.

Vincent's stomatitis is becoming recognized as a distinct clinical entity. This disease may appear as the end result of many debilitating diseases. More often it appears in healthy individuals, but its main requirement to appear in epidemic form is poor mouth hygiene and crowded quarters.

Confronted by an epidemic of Vincent's stomatitis in an institution in which end results could be observed, we decided to give nearly every logical treatment a fair trial and observe the results.

It had been proved that Vincent's organisms are obligate anaerobes and cannot exist in the presence of oxygen; consequently we would resort to oxidizing agents for assistance when our cases did not do well. The pathogenicity of these organisms is still questioned, but destruction of these organisms eradicated the pathologic condition.

Leeuwenhoek<sup>1</sup> in 1683 told the Royal Society about a new kind of creature that he found in the mouth of a virtuous but dirty individual. This mouth was host to an organism that slid among the others, bending its body in graceful curves. Two hundred years later Pasteur<sup>2</sup> discovered that each infectious disease is produced by a specific organism. In 1883 Willoughby D. Miller, an American dentist, described fusiform bacilli and spirochetes. He stated that "pathogenetic properties of these organisms had already been described by Verneuil and Clado." Plaut<sup>3</sup> in 1894 reported cases of nondiphtheric membranous angina in which he found the organisms described by Miller. He called these "Miller's organisms." He attributed them to be the causative factors in the angina because the organisms were present in such great numbers. The organisms are found beneath the free margin of the gums in almost every mouth.

was regular until seven months before admission; since then she had missed four periods. There was frequency of urination during the day and nocturia two or three times a night. Increasing fatigue and nervousness were noted. She was conscious of "throbbing in the heart region." Palpitation was aggravated by exertion.

In the last few months pain developed in the right lower quadrant of the abdomen sufficiently severe to force her to seek admission to the hospital. There were no digestive disturbances.

The patient was obese with face flushed, skin moist and hands showing fine tremors. There was a suggestion of exophthalmos with some widening of the palpebral fissures. The neck showed rather moderate fulness, but not out of proportion to the rest of body configuration. The palms of both hands were moist. The heart showed left ventricular hypertrophy, the apex beat forcible and diffuse, tachycardia, the first sound loud, and no murmurs. The blood pressure was 150 systolic, 75 diastolic. There was muscular relaxation throughout the abdomen. No areas of plus tension were present and no masses were palpable. There was some tenderness on digital palpation in the lower right quadrant. There was uniform fat distribution with predominance over the hips and upper part of the thighs. The pelvic organs were normal. Roentgenograms of the chest showed slight prominence of the left border of the heart in the region of the left auricle. Otherwise the chest appeared normal. The sella turcica was normal on x-ray examination.

The laboratory examination revealed normal urine, a lymphocytosis of 40 per cent, Wassermann reaction negative, and sugar tolerance, fasting, 86 mg. per hundred cubic centimeters of blood, one-half hour 190 mg., one hour 150 mg., and two hours 144 mg.

Because of the tachycardia and nervousness and easy fatigability a basal rate was taken and found to be plus 43 and plus 47 on two different occasions.

The patient was placed on compound solution of iodine 0.6 cc. three times a day. At the end of twelve days the pain in the right lower quadrant of the abdomen ceased; nervousness was diminished. The basal rate had fallen to plus 2. The patient left the hospital and continued to report to the metabolic clinic for three weeks in a much improved state. Because of some "quarrels at home" she became nervous and irritable, with a return of all the former symptoms. The patient was advised to return to the hospital for thyroidectomy. She refused and failed to return to the clinic.

That the abdominal pain simulating an acute appendicitis is due to hyperthyroidism is evident from the facts that the pains were not associated with digestive disturbance, and administration of compound solution of iodine and the general improvement of the hyperthyroid state were followed by complete cessation of abdominal symptoms. With a return of hyperthyroid symptoms the pain in the right lower quadrant reappeared.

The cause of abdominal symptoms is not well understood; however, they may be due to disturbances of the vegetative nervous system. The existence of a disturbed vegetative nervous system in hyperthyroidism is well known and is evidenced by the dermographism and easy blush that the hyperthyroid patient shows.

It is quite possible that the abdominal pains are conditioned by the patient's constitutionalanlage, associated with disturbed gastric hypersecretion and spastic bowel. The hyperthyroid state merely aggravates the abdominal signs. The existence of a complicating intra-abdominal surgical lesion is difficult to exclude without an exploratory laparotomy. However, the fact that the abdominal symptoms disappear with other signs of hyperthyroidism when iodine is given and reappear with symptoms of thyrotoxicosis when iodine is omitted would lead one to assume that they are related to hyperthyroidism.

*CASE 3.—Hyperthyroidism masked by pain in the left upper quadrant of the abdomen; complicated by constitutional syphilis; antisyphilitic treatment failed to relieve the abdominal pain; compound solution of iodine abolished abdominal symptoms.*

Mrs. J. B., aged 24, a Negress who had two living children and had had one miscarriage, admitted to the Philadelphia General Hospital in the service of Dr. H. D. Jump, Oct. 22, 1934, complained of violent pain in the left side of the abdomen near the umbilicus. The pain had been of two days' duration, was localized in the midabdomen with no area of transmission, was associated with belching and was made worse by the intake of food, especially fried food. There was no nausea, but she vomited once because she took large quantities of sodium bicarbonate to induce vomiting for the relief of pain. The bowels were obstinately constipated.

She stated that for the past twelve months she had been feeling generally out of sorts and unusually nervous and fidgety, having frequent attacks of palpitation and vague, diffuse complaints. The digestive upsets were usually worse during menstruation. One month before admission, during menstruation, pain developed in the epigastric region. There were copious eructations of gas. Two days prior to her admission to the hospital she was seized with acute pain in the upper left side of the abdomen. The appetite was good; she drank large quantities of water and had lost 20 pounds (9 Kg.) in the last year.

Examination revealed that the patient was very thin and nervous and weighed 76 pounds (34.5 Kg.). The skin was warm but dry. The eyes showed some widening of the palpebral fissures. The thyroid was definitely enlarged, the right lobe more so than the left; it was firm and smooth and was not adherent to the underlying structures. The heart was of normal size and overactive, with a soft systolic murmur over the apical and pulmonic areas. The lungs were clear throughout. The blood pressure was 170 systolic, 100 diastolic. The pulse ranged from 100 to 120. The abdomen was scaphoid in type; peristalsis was hyperactive. The liver was of normal size. There was tenderness on deep palpation in the left upper quadrant. The spleen was palpable. The deep tendon reflexes were exaggerated. There were no clinical signs of neurosyphilis. The pelvic organs were normal.

X-ray examination of the chest showed normal lung fields and cardiac silhouette except for an enlargement of the pulmonary conus. Both diaphragms were normally outlined. There was evidence of splenic enlargement. Urinalysis was normal. The blood count showed a secondary hypochromatic type of anemia, the red blood cells being 4,520,000 and the hemoglobin 60 per cent. (Dare hemoglobinometer). The blood sugar was 100 mg. per hundred cubic centimeters, the blood urea nitrogen 12 mg. The Kahn and cholesterol antigen was 4 plus. The basal metabolic rate was plus 85 per cent. The electrocardiogram showed sinus tachycardia.

The patient was given compound solution of iodine 10 minims (0.65 cc.) three times a day, rest in bed, sedatives and high carbohydrate diet. This regimen was continued for two weeks. The abdominal symptoms disappeared and the spleen was no longer palpable. The pulse rate came down to 80, blood pressure to 135 systolic, 80 diastolic, and she gained about 4 pounds (1,814 Gm.). The basal metabolic rate decreased to plus 34 per cent.

It was suggested that the syphilitic infection might be the underlying factor for the hyperactivity of the thyroid gland. Compound solution of iodine was stopped and antisyphilitic treatment was administered, consisting of biweekly intramuscular injections of bismuth potassium tartrate for three weeks. The patient's pulse rate rose to 110; she became nervous and the basal metabolic rate became elevated to plus 45. The pain in the abdomen recurred, although not in as severe a degree as when the patient was first admitted to the hospital. The antisyphilitic treatment of weekly intravenous injections of neoarsphenamine 0.6 Gm. and a bismuth compound intramuscularly was continued for two weeks. The patient gained weight but the pulse rate remained accelerated and the basal metabolic rate remained high (plus 33). Potassium iodide was administered one week later the basal metabolic rate decreased to plus 17. She left the hospital over the Christmas holidays in a much improved state.

when solution of hydrogen peroxide was used as a gargle. Therefore we have limited the scope of this paper to Vincent's stomatitis, with which we have had a great deal of experience. We feel that this disease is very common and, if recognized and properly and promptly treated, the results will be excellent and the patients will not be endangered either by the complications or by overmedication.

In the last two and one-half years, 3,800 patients have been examined at least ten times. We never found Vincent's ulcer in a mouth from which the teeth have all been extracted. This was also observed by Bloodgood.<sup>8</sup> Our edentulous patients numbered 325. We have never found Vincent's infection in the mouth of a tobacco chewer. This agrees with Moriarty.<sup>10</sup> In our series ninety tobacco chewers have given negative results at each examination. Smokers seem to be more susceptible to infection and reinfection. The constant use of cigarets sets up a gingivitis in the lower anterior region which makes the individual very susceptible to Vincent's infection.

Of 450 slides taken of patients with mild to severe gingivitis, 212 showed numerous Vincent's organisms without ulceration. This occurred some fourteen months ago. These patients have been carefully watched and of this number Vincent's stomatitis developed in only twelve. The others are clear at this date. Therefore we conclude that Vincent's organisms can be found in many normal mouths and are not indicative of the disease. This agrees with Tenny, Lichtenberg, Werner and Lueck<sup>7</sup> and others.

Irritation and gingivitis from poor fitting dentures, poor alinement of the teeth and broken down teeth, according to Harrell,<sup>11</sup> are anaerobic incubators and provide excellent spots for the infection to start. In our observations we also find that pyorrhea pockets, overhanging fillings and gingival tissue flaps also are contributing factors. We had six patients who were under heavy arsenic treatment for syphilis and developed Vincent's infection. Sutton<sup>12</sup> and others have observed the same phenomenon.

Poor nutrition may be a factor, according to Fantus,<sup>13</sup> but in our patients we could not attribute it to such a lack, since our epidemic was not from certain wards but from the whole institution. From the wards caring for patients of the lowest mentality and where the younger patients are confined, among whom the personal hygiene is at the lowest ebb, we found the largest number of cases. While the epidemic was at its height we had a corresponding increase in our private practice.

Eight patients were examined for blood calcium during acute infections, and eight others who had had the infection and who had been dismissed as cured were also examined. The blood calcium content in all cases, both acute and cured, was within normal limits. At the same time a complete blood count was taken in the active cases and all were within normal limits, a few cases showing a slight polymorphonuclear leukocytosis.

Vincent's infection in cases of even the most severe type does not establish any immunity, as many patients return with new infection.

The following is a summary of our results with the recognized methods of treatment. In spite of the fact

that we had six syphilitic patients under active anti-syphilitic treatment with arsphenamine in whom Vincent's stomatitis developed, we decided to try twenty-three patients on neoarsphenamine, 3 Gm. in three doses, and allow these patients to use their ordinary mouth hygiene.

CASE 1.—One of the patients with Vincent's stomatitis was given intravenous injections of neoarsphenamine; the infection healed rapidly and negative smears were obtained from his mouth. He was dismissed as cured. In about fourteen days he returned with a cellulitis on the right side of the face and throat, the free margin of gums and cheeks showing a characteristic Vincent's ulcer from which positive slides were obtained. He was then treated with hydrogen peroxide 10 per cent, neoarsphenamine and glycerin, but the ulcer persisted and enlarged. A dull red spot appeared on the external surface of the cheek in thirty-six hours and changed to black. This rapidly started to slough away and with it sequestrums of the maxillary bone, deciduous teeth and unerupted permanent teeth. This extensive destruction of tissue was not accompanied by hemorrhage. There was a characteristic foul odor from the patient, which could hardly be tolerated even in the presence of disinfectants. The patient did not complain but persisted in picking at the ulcerated part. The diagnosis was noma. On the sixth day following the onset of the infection the patient died.

While on the subject of noma we will give brief outlines of two other cases that came under our observation:

CASE 2.—A white girl, aged 12 years, who had been under treatment for Vincent's infection, had been dismissed as cured after the mouth had cleared up and all symptoms had disappeared. Two months later she returned to the office for treatment. She had a small ulcer the size of a dime (18 mm.) in the buccal mucous fold on the upper right side of the mouth with some ulceration of the gums, an oral temperature of 101 F., marked fetid odor of the breath and diarrhea. She was given one injection of neoarsphenamine and treated with 10 per cent neoarsphenamine and glycerin followed by spraying with solution of hydrogen peroxide, U. S. P., every two hours. In spite of all treatment, however, the patient grew rapidly worse. The ulcer progressed rapidly, eating through the soft tissue into the bone, causing the loss of several teeth. Finally it penetrated into the antrum. The sixth day after the institution of the treatment, death occurred. The entire right cheek including the eye was sloughing away when death occurred. Positive slides were removed from the ulcer.

CASE 3.—A Negro boy, aged 10 years, presented a clinical picture identical with that just reported except that the ulcerative spot was on the lower left side. Considerable cellulitis was present. Under anesthesia we did a radical extirpation of the ulcerated area. We then cauterized the area with 50 per cent trichloroacetic acid. A two-hour treatment with solution of hydrogen peroxide was instituted and in two weeks complete resolution was obtained. Up to the present time the patient has never had a recurrence. He has been examined ten times since the treatment, so we will suppose that he is completely cured.

Of the other cases under neoarsphenamine treatment, the condition in four cleared up and remained well. Several others showed a marked change for the better in from two to four days. However, this treatment did not go to complete resolution but responded to local treatment by solution of hydrogen peroxide. Any medication that is as widely acclaimed as the arsenics should be a specific for this condition. We feel that it has little therapeutic value intravenously. This agrees with a statement in THE JOURNAL: "Intravenous injection of neoarsphenamine has never been justified in the treatment of Vincent's infection, either theoretically or clinically."

In the treatment of a large number of cases with a limited staff it would be impossible to use sodium per-

temperature and is minimal when the air is warmed. The effect of the air currents in increasing evaporation from the skin may be considerable. It should be minimized by a deflector over the entrance of the hose from the pumping unit, so as to prevent the full blast of the suction and pressure from striking the limb.

That the cooling of a limb will normally cause considerable contraction of the arterial system has been known for some time,<sup>1</sup> and Reid and Herrmann<sup>2</sup> have pointed out that cooling may produce an actual blanching in the presence of diseased arteries.<sup>2</sup>

There are various methods for the relief of vasospasm. Fever therapy, while an excellent method, is not suited for repeated daily use. The same is true of anesthesia (local, spinal or paravertebral). Vasodilating drugs are unsatisfactory: mechlorin, the most powerful, is too expensive for routine use, theobromine is too uncertain and alcohol is too weak. One is left with the increase of environmental temperature as by the warming of the body by blankets and heaters<sup>3</sup> or by the heating of one or two of the limbs not being treated; e. g., heating the arms when the legs are treated<sup>4</sup> or, finally, by the heating of the diseased limb itself. For actual use during suction pressure treatment two methods have been used to give vasodilatation through heat. Landis and Gibbon<sup>5</sup> put to use the mechanism of their vasodilatation test and immersed the arms in warm water while the legs were in the apparatus. Later Landis and Hitzrot<sup>6</sup> used an electric heating pad around one arm as the source of heat. Reid and Herrmann<sup>1</sup> use preheated air at from 102 to 105 F. to heat the treated limb and in addition prescribe whisky.

A perusal of the measurements of the increase in blood flow caused by these various vasodilating procedures leads one to believe that the most powerful of all these agents is heat applied to the treated limb. Mosso's<sup>7</sup> graphs demonstrate that when both forearms are placed in separate plethysmographs, and only one is heated, both pulse waves increase in height but the increase is much more marked on the heated side.<sup>8</sup> Lewis,<sup>9</sup> by measurements of the digital pulse volume, and Hewlett and his associates,<sup>8</sup> by measurements of blood flow in the forearm and hand, have shown that

the application of local heat will increase the blood flow from four to eight times. Freeman<sup>10</sup> has also measured blood flow by a plethysmographic method modified from the latter authors. His curves show the same rise of blood flow with increase in local heat, and it can be seen that as soon as the local heat reaches 30 C. (86 F.) or higher this increase greatly surpasses that from sympathectomy. Normally there continues to be an increase in blood flow with rise in temperature at least up to the point where the local heat reaches 50 C. (122 F.).<sup>11</sup>

There are reasons for believing that unless blood flow is additionally increased by other means, as by suction, the exposure of limbs with organic arterial obstruction to high levels of heat is harmful and may be dangerous. This can be demonstrated in an exaggerated degree by comparing the effect of large doses of diathermy when used on a live normal limb and the effect of the same amount of current on a piece of beef. In the live limb the heat is carried away as it is formed, while the heat remains in the piece of beef because there is no circulating medium to carry it away, and the interior of the beef becomes cooked. In considering lesser degrees of heating and its effect on the tissues

The device, attached within the treatment cylinder, to warm the limb undergoing suction-pressure treatment. (Made by Warren E. Collins, Inc., Boston.)

in the presence of organic arterial obstructions, Freeman<sup>10</sup> has considered that such heating is distinctly harmful. His reasoning follows from his conclusion that local heat produces vasodilatation because the heat increases the local metabolism of the tissues. When the arteries are normal, the increased need for nutriment is upheld by the augmented blood supply. When organic obstruction is present, however, the increased metabolism causes a quicker utilization of whatever blood can enter the limb. This being already inadequate, tissue starvation is increased. In this way local heat may cause considerable increase in the symptom of pain and may initiate or increase gangrene.

While it is certainly necessary to keep this in mind, the increase in blood flow during suction in the apparatus is ordinarily quite adequate to take care of the increase in metabolism caused by local heating. An important aspect of using heat during the time that a sufficient blood flow is enabled to enter the limb is that emphasized by Herrmann.<sup>1</sup> He points out that the local

11. When increase in circulation is obtained by producing general artificial fever, Johnson and others have shown that a maximum increase in the height of the pulse wave is reached when the body temperature lies between 103 and 104 F. and seemingly will go no higher when the fever temperature is raised beyond this point (Johnson, C. A.; Osborne, Stafford, and Scupham, George: Studies of Peripheral Vascular Phenomena: IV. The Effect of Artificial Fever on the Pulse Volume Changes of the Finger, *Am. J. M. Sc.* 190: 485 [Oct.] 1935).

1. Mosso<sup>1</sup> measured the height of the pulse of the hand and forearm by immersing the limb in a plethysmograph in which the temperature of the water could be changed. He used temperatures as low as 13.8 C. Hewlett, van Zwaluwenburg and Marshall<sup>8</sup> used a similar plethysmograph but took measurements of the amount of arterial inflow per unit of time. Using water at low temperatures, down to 12 C., they noted a fall in the circulation rate of from one-fourth to one-half the flow at ordinary room temperatures.

by Abramson,<sup>2</sup> who had observed eight such patients. Toomey<sup>3</sup> has recently reported the occurrence of the disease in seventy patients.

Considerable controversy has arisen with regard to the possible etiology. Many clinicians hold to the belief that the disease is a form of epidemic encephalitis or of poliomyelitis, while others consider it to be a separate and distinct disease. There have been few

reports concerning the etiologic factors of this disease. Eckstein<sup>4</sup> injected the cerebrospinal fluid of three patients having this type of meningitis into the spinal canals of monkeys and observed a meningomyelitis in one animal but no changes characteristic of poliomyelitis or encephalitis. Rivers and Scott<sup>5</sup> were able to produce in animals a meningeal reaction with an increase in the number of mononuclear cells by injections of cerebrospinal fluid obtained from two patients with aseptic meningitis. These patients slowly developed in the blood serum antibodies to this virus. The strain of virus obtained in these experiments was similar to that found by Armstrong and Lillie,<sup>6</sup> who isolated from patients of the St. Louis epidemic of encephalitis a strain that produced a choriomeningitis in animals. Subsequently Armstrong and Wooley<sup>7</sup> reported that they had found two additional strains of this virus in experimental animals and that specific antibodies had been discovered in the blood serum of some uninoculated animals and in one person who had recovered from an attack of choriomeningitis eleven months previously.

Our purpose in this report is to present the characteristics of an epidemic of atypical meningitis in Cincinnati in 1935. Twenty-two children were observed in the Children's Hospital and in the pediatric wards of the Cincinnati General Hospital.

REPORT OF EPIDEMIC

All but three patients of the group of twenty-two contracted the disease in the summer months. The disease was fairly uniformly distributed throughout the various age groups (table 1). Several adults in the community were said to have developed symptoms of this illness during the same period but none of them came under our observation and are not included in this report. The racial distribution was similar to that of the average population of our two hospitals.

The majority of the children were referred to the hospital because of suspected meningitis. The onset of illness was reported by the parents to be sudden in twelve cases and in no instance had the child been sick more than a week before admission to the hospital. The frequency of the symptoms and physical signs of the illness are recorded in table 2.

Headache, practically always present, was located in the frontal region in eight children, but in no instance was the symptom as severe as usually encountered in

meningococcic meningitis. The pain was alleviated by the withdrawal of from 10 to 50 cc. of the cerebrospinal fluid, which was usually found to be under greater pressure than normal. Vomiting was not projectile and tended to disappear as the general condition of the patient improved. Mild sore throat, rhinitis and nasopharyngitis were noted in fourteen patients and were included under the heading of infections of the upper respiratory tract. Otitis media was not present imme-

Two of these five persons had streptococcic sore throat while the doses were being given, in both instances from two to three weeks previous to the dose causing the joint pains. One of the patients had scarlet fever as a child. One had frequent sinusitis of unknown etiology before her tonsils were removed, and one gave a history of growing pains with occasional sinusitis as a child.

These results indicated that the joint pains were not produced by protein contained in the veal broth used in preparation of the toxin. The following experiment was undertaken to learn whether the arthralgia was caused by substances other than the soluble toxin produced during growth of scarlet fever streptococci in the broth:

#### SECOND EXPERIMENT

Fifty-eight young adults who had positive Dick tests and who were being immunized against scarlet fever reported the occurrence of joint pains. One week after the administration of the dose that produced the joint pains the next larger dose was given, but this toxin was heated before injection by immersion in a bath of boiling water during one hour. This length of time has been shown to be sufficient to inactivate all soluble toxin in the solution. The following week the same dose was given. However, on this occasion the material was unheated and therefore contained active toxin.

The reaction was noted after each dose and the foregoing procedure was repeated each time the patient reported joint pains. To eliminate so far as possible the subjective element, the patients were given no information concerning the boiled toxin injections. They assumed that all doses contained unmodified toxin. A

history similar to that in the first experiment was obtained. The patients in this experiment fell into four groups:

Group 1. Those patients in whom joint pains occurred on injection of unmodified toxin and were absent after the injection of heated toxin, with recurrence of pains on one or more subsequent injections of unheated toxin.

Table 2 indicates the nineteen persons in this group. Their joint pains, when they occurred, were severe and definite, coming on within twelve hours after unheated toxin was administered and lasting for from one to five

days. At the end of a seven day period joint pains had completely disappeared and did not recur in any degree whatever following the administration of heated toxin. After another week had elapsed a dose of unheated toxin again caused marked joint symptoms similar to those observed at the first occurrence among these patients. Three of the nineteen patients gave a history of previous definite joint involvement; in one instance rheumatic fever had occurred four years previously; in one instance "arthritis" had been associated with scarlet fever twelve years previously, and in another instance "arthritis" had been associated with recurrent tonsillitis of unknown etiology. Three of the nineteen patients reported frequent sore throats before removal of the tonsils and gave evidence of cardiac involvement, two of the three presenting systolic murmurs. Five of the nineteen patients gave a history of definite growing pains as children, in one instance associated with sore throat and tonsillitis, while six of the nineteen had apparently had uncomplicated sore throat or tonsillitis, three frequently and three occasionally. Two patients gave no history of any of the foregoing symptoms.

Group 2. Those patients in whom joint pains occurred on injection of unmodified toxin and who had no pain after injection of heated toxin and no recurrence of pain on subsequent injection of unmodified toxin.

Table 3 indicates the twenty-three persons in this group. They had definite joint pains once during the course of immunization followed by the absence of such pain after the administration of heated toxin, but they had no joint pain after the next dose of unheated toxin. Six of these twenty-three persons gave a history of previous joint involvement, two of them following scarlet fever in one instance twenty-five years previously and the other fifteen years previously and more recently following sinusitis, one following accidental injury to a knee, two associated with growing pains or sore throat

*Differential Diagnosis.*—Several diseases involving the central nervous system resemble in their symptomatology the type of illness described in this group of children. In the presence of an epidemic of poliomyelitis we would have suspected an abortive form of this disease, but the absence of a single case of paralysis in the community led us to doubt such a diagnosis. Negative Wassermann or Kahn tests of the cerebrospinal fluid tended to eliminate the presence of syphilis of the central nervous system. The blood of one patient, known to have syphilis, gave a positive Kahn reaction but his cerebrospinal fluid was negative with both the Kahn and the colloidal gold test. Only two patients had positive tuberculin tests on admission and there were no signs of tuberculous infection in this group except one instance of suspected hip joint infection. The absence of tubercle bacilli in the cerebrospinal fluids of the patients examined and the normal quantitative sugar determinations of the fluids indicated the absence of tuberculous infections. Several guinea-pigs inoculated with the material obtained from lumbar puncture remained well. The rapid recovery of this group of patients likewise spoke against tuberculosis. The diagnosis of encephalitis was more difficult to eliminate, but opposed to it were (1) the facts that cranial nerve involvement was absent except in the two instances of ptosis and unilateral facial weakness mentioned, (2) meningeal symptoms and signs predominated, and (3) the patients made rapid and complete recoveries.

*Treatment.*—Besides the removal of cerebrospinal fluid to relieve the intracranial pressure, treatment was limited to sedatives. Phenobarbital, codeine and morphine were used to relieve the headache and discomfort of lumbar puncture. It was necessary to continue treatment for only a day or two and the symptoms were much more mild and of shorter duration than those accompanying meningococcic meningitis.

*Residual Symptoms.*—Four children were examined at fourteen day intervals for a period of six weeks after the onset of their illness. These children had made complete recoveries and the cerebrospinal fluids were entirely normal at each examination. Twelve of the group of children were examined from six to eight months after they had recovered from their attacks of benign lymphocytic meningitis. In no instance was there found any change in cranial nerve function, in the deep and superficial reflexes, or in the muscle power and coordination. The children were in a satisfactory state of nutrition, had shown no abnormalities of behavior and had performed their school work in the usual fashion. Similar information was obtained from the physicians or parents of two additional children.

#### COMMENT

The characteristics of this disease indicate that it is a clinical entity. The criteria suggested by Wallgren for the diagnosis of the condition were fulfilled in this epidemic. We prefer the designation "benign lymphocytic meningitis" to "aseptic meningitis." Benign lymphocytic meningitis may have occurred much more frequently than the reports in the literature indicate, and without doubt this symptom complex has frequently been diagnosed as an abortive form of poliomyelitis, encephalitis or meningococcic meningitis. Occasionally benign meningeal reactions diagnosed as serous meningitis or lymphocytic meningitis occur in children coincident with such diseases as pneumonia,

otitis media or mastoiditis, typhoid fever or streptococcic infections, but they do not belong in the category of benign lymphocytic meningitis. Whether or not the etiologic agent of this type of meningitis is related to that of poliomyelitis or of encephalitis will have to await further bacteriologic investigation. It is certain that the clinical symptoms, as we have observed them, differ in many ways from either of these diseases.

The disease does not appear to be contagious. Two of our group of patients were siblings of the same family and developed the disease one week apart. One child, who lived directly across the street from another patient, developed the illness several weeks after any possible exposure to the illness. Otherwise the children came from widely separated parts of the community with little likelihood of contact with one another.

During the winter preceding the epidemic of benign lymphocytic meningitis there was an unusually high incidence of meningococcic meningitis in the community. In the spring of that year a few patients had meningeal symptoms associated with mumps. At the peak of the epidemic of benign lymphocytic meningitis, more than seventy children who had contracted pleurodynia were observed in the two hospitals. One of the patients, who developed benign lymphocytic meningitis, had recovered from an attack of pleurodynia one week before the onset of the meningeal symptoms. At the same time a severe form of diarrhea developed in newly born infants in the nurseries of several hospitals, and this disease was accompanied by a severe toxemia and a high mortality rate.

The incidence of other diseases in the community was about the same as in other years. No cases of poliomyelitis were reported in the community for a year before or after the epidemic of benign lymphocytic meningitis, and only an occasional patient with encephalitis was observed during the same period of time.

#### SUMMARY

1. Symptoms of benign lymphocytic meningitis were observed in a group of twenty-two children during the year 1935.
2. The peak of this small epidemic occurred in the months of July and August. The disease developed in widely separated areas of the community except in two instances, so that contact with known patients could not have been responsible for its spread.
3. Characteristic symptoms of the disease were headache, vomiting and abdominal pain. On physical examination rigidity of the neck and positive Kernig and Brudzinski signs were most frequent.
4. Most of the cerebrospinal fluids contained from 50 to 200 cells, chiefly lymphocytes, and the globulin content was greater than normal in about half of the group. The fever was of short duration, and in nineteen of the twenty-two cases the leukocytes of the blood were not increased above normal figures.
5. Recovery was rapid and complete. More than half of the group were examined from six to eight months after recovery from the disease but no evidence of residual symptoms and signs or of changes in behavior could be discovered.
6. The mildness of the infection, its epidemic characteristics and the absence of any other disease in the patients or in the community to account for the illness has led us to suspect that it was a definite disease entity, possibly of a virus nature.

In 1898-1899 Vincent<sup>4</sup> described two diseases of the mucous membrane of the mouth and pharynx which he ascribed to a spirochete. The first was mild stomatitis, with superficial ulcerations, with a subfebrile course lasting two weeks. The second was more severe. In the mild case he found only the fusiform bacillus and in the more severe he found the bacillus associated with the spirillum. He was unable to cultivate the organisms and satisfactorily test their pathogenicity, being unable to produce the disease in the mouth or vagina of animals. Weaver and Tunncliffe<sup>5</sup> in 1905 described the presence of the fusiform bacillus and spirillum in ulcerative stomatitis and succeeded in cultivating the bacillus anaerobically.

Smith,<sup>6</sup> in an attempt to prove the pathogenicity of these organisms, was unable to produce abscesses in the groins of guinea-pigs without first traumatizing the tissue. In 20 per cent of some 100 animals Smith produced lung abscesses by intratracheal injections of bloody scrapings from pyorrhea under ether anesthesia. He concluded that lung abscess was commonly caused by a mixture of anaerobic organisms, the fusiform bacillus, spirochetes, vibrios and a hemolytic streptococcus. Smith made spirochete cultures of these organisms and injected guinea-pigs with pure culture singly and combined. Only a mixture of *Treponema microdentium*, a small fusiform bacillus, a vibrio and hemolytic streptococcus would produce the typical foul smelling pus.

Lichtenberg, Werner and Lueck,<sup>7</sup> at the suggestion of Dr. Joseph Brennemann, have made some of the most significant observations with regard to the clinical course of treatment and the failure of many works to establish the pathogenicity of these organisms. They had sixteen ulcerative cases presenting positive Vincent's organisms which cleared up without treatment. It has been our observation, however, that the manifestations of the disease became more acute the longer they were allowed to progress without treatment; finally the patient would refuse food and drink, owing to the pain caused by the ordinary processes of mastication and swallowing.

Vincent's stomatitis is a mildly contagious disease which commonly affects the gums and in the more severe cases the lips, cheeks and lateral and dorsal aspects of the tongue. This may be followed or preceded by Vincent's angina and involvement of the entire respiratory and gastro-intestinal tract.

The disease is as Bloodgood<sup>8</sup> so aptly described it:

The mucous membrane lining the three communicating chambers—oral cavity, fauces and pharynx—may be diffusely involved or there may be only a single spot a few millimeters in diameter. The single spot is the unit, and the diffuse lesion is only a multiplicity of single spots. The single spot is at first a red area of irregular outline, never sharply defined, of such a peculiar redness that it may be called the erysipelas of the mouth. The center of the red area may be covered with a whitish or grayish patch which is really due to the superficial destruction or necrosis of the red mucous membrane. Beyond this superficial slough there is still a red zone. It is not unlike a minute gumma in which a central zone of necrosis, surrounded by the red zone of collateral anastomoses of increased vascularity, is recognized. In this stage, because of the little

gray or whitish slough, the condition may be confused with leukoplakia, but the latter is never surrounded by an inflamed and reddened mucous membrane. Leukoplakia and Vincent's angina may appear together. In the next stage the slough comes away and leaves an ulcer. Thus there may be, in this infection called Vincent's angina, single or multiple red areas, single or multiple areas covered with a superficial slough, or single or multiple ulcers. Now and then one or more of these ulcers may be quite large, although rarely more than 18 mm. in diameter; usually the single unit areas are only a few millimeters in diameter. The ulcer never looks like a mucous patch, and it never has the ragged excavated edge of the tuberculous ulcer or the induration of the cancerous ulcer. In the very extensive cases there may be a fibrous exudate not unlike diphtheritic inflammation.

The disease as we observed it clinically was characterized by pain and swelling of the gums, hyperemia, and fetid odor of breath. The gums were often covered with a gray pseudomembrane, more common in the interproximal spaces than elsewhere. The removal of this membrane produced profuse bleeding. The interproximal papillae are destroyed by ulceration and sloughing, producing a characteristic punched out appearance which persists even after resolution. There is a septic type of temperature varying from 97 to 103 F. at no fixed time or period. Chills and fever are sometimes present and in more severe cases there is a marked diarrhea accompanied with a loss of weight due to dehydration. The saliva is thick, ropy and excessive. The patient is listless and irritable and refuses to eat in most cases.

Vincent's stomatitis must be differentiated from syphilis, diphtheria and malignant growths, less frequently from scurvy, pernicious anemia, aplastic anemia, acute leukemia, bismuth or mercurial stomatitis, and mouth manifestations of erythema multiforme and pellagra. This differentiation must be accomplished by examination of the blood, and biopsy as well as by negative or positive smears.

In our series of 704 institutional cases (349 females and 355 males) and ninety private cases there were many complications with six deaths. We found it to attack the larynx, the tracheal bronchial tree, as Jackson<sup>9</sup> has observed, producing bronchopneumonia and lung abscesses. It also produced acute suppurative otitis media and two fatal cases of noma. In private practice we were called to see three patients who were dying following the extraction of teeth in the presence of a mild Vincent infection. These patients had extensive ulcerations involving the rectum and genitals, from which pure cultures of Vincent's organisms were obtained. Their blood streams did not show the Vincent organisms. These patients seemed to die of severe toxemia and dehydration due to excessive diarrhea.

Our original intention was to record Vincent's infection in all its phases. However, as the data accumulated we were faced with a limited number of each type of complication. For instance, we had three patients with lung abscess presenting pure culture of Vincent's organisms who recovered with the aid of bed rest and bronchoscopic and postural treatments. We also had many patients with acute otitis media who readily recovered with douchings of solution of hydrogen peroxide. In one case suppurative mastoiditis developed; the patient was operated on and recovered with the usual surgical treatment plus douchings of solution of hydrogen peroxide in the wound. In other cases angina developed, usually accompanied with a stomatitis. The patients with angina would recover promptly

trose were given by hypodermoclysis and two hours later 50 cc. of 50 per cent dextrose intravenously. Shortly thereafter, 5 cc. of liver extract derived from 500 cc. of whole liver was injected intramuscularly. Four hours after admission a tracheotomy was performed, giving immediate relief from dyspnea and cyanosis. Despite intensive treatment, which included two blood transfusions of 500 cc. each, the parental administration of liver extract, pentnucleotide and clyses of saline solution and dextrose, the patient became progressively worse and died on the day following admission. He remained conscious and rational to the end.

**Autopsy.**—Postmortem examination, performed by Dr. Lincoln Oppen of the department of pathology, was made two hours and fifty minutes after death. Jaundice was pronounced. There was marked nonfluctuant swelling of the anterolateral aspects of the neck, which appeared to involve the chains of anterior cervical lymph nodes. The posterior chains of cervical lymph nodes also were somewhat enlarged. The uvula, posterior third of the tongue, tonsils, epiglottis and pharynx as far down as the larynx were covered with a green-black sheet of necrotic exudate, which was unusually thick, measuring several millimeters in places. At a few small points this exudate had sloughed off, revealing tissue that had a red and hemorrhagic appearance. On examination of a preparation of the laryngeal portion of the pharynx taken from an area that was only moderately involved in the process, the tissue was seen to be completely denuded of its necrotic, stratified, squamous epithelium. A dense band of pink fibrin filled the loose meshwork of connective tissue. The walls of almost all the small vessels were necrotic. The muscle tissue in this region had lost its striations and in many places stained a smudgy gray-blue. The complete absence of the type of cell, the neutrophilic leukocyte, usually observed in a necrotizing process of this kind, was striking. A few lymphocytes and an occasional plasma cell were seen. A preparation from another portion of the pharynx presented a similar picture, but it included a portion of a lymph node which was completely necrotic in its central portion.

The edges of the tracheotomy wound were gray, ragged and necrotic. There were small subepithelial hemorrhagic zones about the wound. Microscopic examination of a section of the trachea revealed a relatively intact epithelial lining, beneath which, however, the connective tissue was filled with extravasated red blood cells, but there was a complete absence of neutrophilic leukocytes.

Except for extreme engorgement of the right side, particularly the right auricle, the heart was normal. It weighed 340 Gm.

The right lung weighed 450 Gm., the left 600 Gm. The extreme apexes of both lungs were puckered, firm to palpation and apparently fibrous. The absence of yellow-white or gray formations in the clotted blood in the pulmonary vessels, as well as within the heart chambers, was striking. There were extensive subepithelial hemorrhages in the bronchi and particularly the bronchioles. The lumens of these structures contained moderate amounts of tenacious, yellow-red, mucoid material, but the epithelium of the bronchi did not appear grossly necrotic. Microscopic preparations of the deeper lung portions revealed a blurring of the alveolar architecture due to the extreme extravasation of blood edema fluid and large amounts of fibrin into the alveolar spaces. The absence of white blood elements everywhere was striking. Many bacteria were found in the bronchial lumens and within the alveolar spaces. In several places the bronchial epithelium was sloughed off and necrotic.

The spleen was moderately large and very firm. It weighed 290 Gm. On the cut surface the parenchyma had an unusually homogeneous deep red appearance. Microscopically, the malpighian corpuscles appeared normal in number but were definitely smaller and less cellular than usual. The reticulo-endothelial architecture of the red pulp stood out prominently, owing to the complete absence of nucleated blood cells within the sinusoids. These contained only red blood elements.

The liver extended 5 cm. below the costal margin in the mid-clavicular line and 6 cm. below the tip of the xiphoid. It weighed 2,165 Gm. The cut surface of the liver was homogeneous and chestnut brown. On microscopic examination the sinusoids and central veins were seen to be enormously dis-

tended. Cell necrosis was marked about the central veins, but there was no increase of fibrous connective tissue to replace the destroyed cells. The remaining hepatic cells lay singly and contained much yellow-brown pigment in their cytoplasm. Nuclei were frequently missing. In the peripheral portions of the lobules, the cords of cells were relatively intact. The periportal tissue was free of cellular infiltration. The gall-bladder and bile ducts were not remarkable.

The pancreas, stomach and intestine were not remarkable.

The kidneys were unusually large; the right weighed 230 Gm. and the left 250 Gm. On the cut surface the cortices were unusually wide, measuring 8 mm. Microscopically an occasional hyalinized glomerulus was seen. The tubular epithelium was everywhere swollen and the cytoplasm of the cells was granular in appearance. The cell nuclei were frequently absent, and many pink hyaline casts were seen in the tubular lumens. The interstitial tissue was loose and extremely edematous. The adrenals together weighed 20 Gm. and were not abnormal. The pelvic organs were not remarkable.

Examination of the bone marrow was made by Dr. Robert M. Thomas. The usual amount of marrow tissue was present, with no obvious hyperplasia or hypoplasia. The erythroid group was represented by a predominance of normoblasts, with some early and late erythroblasts present but not in unusual numbers. The total number of red cell elements seemed to be from 30 to 40 per cent of the total. There was a marked increase in the number of megalokaryocytes, which were seen in all stages of growth and senescence. Four or five in a low power ( $\times 100$ ) field was the average. These cells were for the most part poorly stained and fragmented, with only the younger mononuclear and binuclear forms staining well. There were a moderate number of large phagocytic cells which contained cellular and other debris within their vacuoles.

The striking feature of the marrow was the absence of mature polynucleated cells, metamyelocytes and myelocytes type C. The bulk of the marrow was composed of young myelocytes, classified as type B, with just enough granules to make up a small clump in one side of the cell. These cells were strikingly uniform in their level of development. It appears as if cell maturation as well as cell multiplication had come to a resting point at a low level.

On postmortem bacteriologic examination the following organisms were isolated: heart blood, *Streptococcus viridans*; lungs, *Staphylococcus aureus*, *Streptococcus viridans*, *Bacillus influenzae*, diphtheroids; liver, *Bacillus coli*, *Streptococcus viridans*; spleen, *Bacillus coli*, *Streptococcus viridans*; kidneys, *Bacillus coli*, *Streptococcus viridans*; trachea, *Staphylococcus aureus*, *Streptococcus viridans*, *Bacillus influenzae*, diphtheroids.

**Anatomic Diagnoses.**—Primary: Acute necrotizing tonsillitis, glossitis, epiglottitis, pharyngitis, cervical lymphadenitis, hypoplastic bone marrow, edema of larynx, wound of tracheotomy, acute bronchitis, pulmonary congestion and hemorrhage, cloudy swelling and edema of kidneys, generalized jaundice. Clinically: Novaldin (aminopyrine derivative) poisoning.

#### COMMENT

There is a growing commercial practice to market familiar drugs or combinations of drugs under trade names with labeling that fails to give a clear and understandable description of the ingredients. In many instances, such as the present case, the true nature of the article is further masked by the introduction of minor chemical alterations. The representations made for these products, sold under distinctive names, are not infrequently beyond those that could be made for the simple drug under its recognized title and, of course, much more difficult to refute. This case serves as an illustration of the harm that may result from this practice.

One may ask the question, as it has been asked for cinchophen,<sup>4</sup> "Is there a safe method for administering aminopyrine and aminopyrine derivatives?" The abrupt onset without warning and the fulminating course of this case, and others that I have seen, lead inescapably to the same conclusion that there is no entirely safe method of administering aminopyrine.

New Haven Hospital.

4. Palmer, W. L., and Woodall, P. S.: Cinchophen—Is There a Safe Method of Administration? *J. A. M. A.* 107:760-765 (Sept. 5) 1936.

borate as a paste. It would be impracticable, owing to the amount of time necessary to pack each patient's interproximal spaces satisfactorily. In a resistive or lower grade patient it would be almost impossible to apply this medication properly because of lack of cooperation. We require a remedy that can be used on the most uncooperative patient with the least amount of difficulty. This automatically rules out the application of sodium perborate paste.

Neosarsphenamine and glycerin 10 per cent was used in sixty-five cases; in half of this number the condition cleared up promptly and the patient remained well. The remaining portion were treated with the arsenic plus solution of hydrogen peroxide, with good results, and all were cured.

Fifteen per cent chromic acid without any oxidizing agent was tried in 281 cases. This had to be abandoned before any cures were effected because after two treatments the procedure proved to be too drastic, causing vomiting, nausea and severe sloughing of the gum tissue. However, when we combined it with solution of hydrogen peroxide we had many recoveries. The disadvantage of this procedure was that the teeth became badly stained and the nausea and sloughing persisted even when the solution of hydrogen peroxide was used in conjunction with the chromic acid.

In private practice ultraviolet rays have been applied in about ten cases, which all cleared up promptly, but solution of hydrogen peroxide, U. S. P., was used every two hours, day and night, in conjunction with the ultraviolet rays. None of these patients had recurrences. The lamp used was water cooled and the light was applied with a quartz applicator. This agrees with the observations of Rasmussen.<sup>15</sup> However, the same reasons we advanced as making the use of sodium perborate impracticable in institutional work apply to the use of the water-cooled ultraviolet ray lamp.

On some 140 cases we tried aconite, iodine and chloroform. After a thorough trial this was discarded because of the extremely bad taste, though not until we had tried it out thoroughly. In the cures we had under this treatment solution of hydrogen peroxide was used in conjunction with the aconite, iodine and chloroform.

Solution of potassium arsenite was not used owing to the lack of cooperation of patients and the poisonous properties of the treatment. It had been recommended by Smith in his book "Fusospirochetal Diseases" but was not practical for our purposes.

We tried aniline dyes in more than 110 cases, namely, gentian violet in fifty-five and methylene blue in fifty-five, with hardly any success. Only a few cases cleared up and in all cases that did clear up we had used solution of hydrogen peroxide as an adjunct to the treatment. These aniline dyes penetrate the cracks in the enamel and discolor the teeth. This also holds true in the case of porcelain and synthetic fillings. This is a definite contraindication of its use.

We tried tincture of benzoin in thirty-five cases. This treatment did no good whatever and was discarded.

#### CONCLUSIONS

1. The severity of the case is determined by the resistance of the individual and the virulence of the infecting organisms. This is aptly illustrated in the different types of patients we handle, the lower grades and younger defective children always being more susceptible.

2. In all cases and under all types of treatment, in order to get a proper lasting cure, we feel that thorough prophylaxis and scaling of the teeth, accompanied by the removal of all mechanical irritations, is as necessary a requisite in the treatment of this disease as the medicinal side of the treatment.

3. Abstinence from cigaret smoking and alcohol is to be recommended during the infection.

4. The slightest surgical procedure, even in the presence of the mildest types of Vincent's infection, is to be avoided.

5. In most cases the disease becomes more acute the longer it is allowed to progress without treatment.

6. Solution of hydrogen peroxide, U. S. P., is the prime factor in curing Vincent's infection. However, some of the cases may be assisted by the use of other medicaments, but one cannot be sure of a cure in all cases unless solution of hydrogen peroxide is used in conjunction with the other medicaments. We also feel that it cannot be used to excess. In referring to the use of solution of hydrogen peroxide in this paper it was always used at least four times a day, full strength. The recoveries were quickened in some cases when it was used more frequently; that is, every two hours, instead of four times daily.

Dixon National Bank Building.

## BENIGN LYMPHOCYTIC MENINGITIS

(ASEPTIC MENINGITIS)

CLYDE M. DUMMER, M.D.

ROBERT A. LYON, M.D.

AND

FRANK E. STEVENSON, M.D.

CINCINNATI

Since the beginning of this century a benign disease characterized by headache and meningeal symptoms has been reported in Europe. Local epidemics of such a disease in France in the years 1910 and 1913 were thought to be abortive forms of poliomyelitis, and in 1922 to 1924 similar epidemics in Europe were ascribed to encephalitis. Wallgren<sup>1</sup> reviewed these reports in 1925 and suggested that the disease, which frequently occurred in epidemics, might be a separate clinical entity and he called it "acute aseptic meningitis." He also suggested that a virus might be the etiologic agent. The criteria he considered necessary for such a diagnosis were (1) an acute onset of meningeal symptoms; (2) changes in the cerebrospinal fluid characteristic of meningeal irritation, with a slight or moderate increase in the number of cells, especially of lymphocytes; (3) sterility of the fluid, both on direct examination and in appropriate culture mediums; (4) a short, mild course of the disease with no complications; (5) the absence of any condition that might lead to meningeal irritation, such as otitis media, sinusitis, trauma, and especially of any acute or chronic infection; (6) the absence in the community of any disease that characteristically involves the central nervous system.

Since Wallgren's review, numerous reports of the disease have been made in this country as well as in Europe. This material has been reviewed completely

From the Department of Pediatrics, University of Cincinnati College of Medicine, the Cincinnati General Hospital and Cincinnati Children's Hospital Research Foundation.

15. Rasmussen, A. T.: *Arch. Phys. Therapy* 15: 676-680 (Nov.) 1934.

This apparatus has a very limited field of usefulness and probably therefore does not belong in the armamentarium of the average physician. It belongs more in the realm of hospital equipment, since most of these rare arterial diseases are hospital cases.

In view of the satisfactory performance of this unit with reference to the treatment of acute vascular occlusion, freezing, and in vascular diseases with major involvement of the large vessels, the Council on Physical Therapy voted to include this apparatus in its list of accepted apparatus.

### CAMERON CAUTERODYNE, MODEL H, ACCEPTABLE

Manufacturer: Cameron Surgical Specialty Company, Chicago.

This is a surgical diathermy unit recommended by the manufacturer for cutting, coagulating, dehydrating, desiccating and fulgurating. It is of the tube type construction and is said to be capable of cutting and coagulating under water. It comes equipped with foot switch and electrodes.

Cameron Cauterodyne, Model H.

The machine operates on alternating current and the wavelength is about 125 meters, or 2,400 kilocycles. The power consumption varies from 150 (2.5 amperes) for cutting to 220 watts (3.5 amperes) for coagulation. The maximum temperature developed inside the cabinet

in using the machine for one hour—one minute on and one minute off—is 150 F.

This unit has been in service under practical conditions for six months in a clinic acceptable to the Council and has been found to be satisfactory.

In view of the favorable report on this unit, the Council voted to include the Cameron Cauterodyne, Model H, in its list of accepted devices.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

**PROTAMINE ZINC INSULIN.**—A preparation of insulin modified by appropriate addition of protamine and a zinc salt. When this modified preparation in its precipitated form is brought into uniform suspension, each cubic centimeter contains 40 units of insulin together with from 0.30 to 0.50 mg. of protamine and from 0.08 to 0.10 mg. of zinc. The preparation contains, in addition, sufficient disodium acid phosphate to maintain its hydrogen ion concentration at not more than that corresponding to  $pH = 7.1$  and not less than that corresponding to  $pH = 7.4$ . This buffering agent, in terms of its anhydrous salt ( $Na_2HPO_4$ ), represents not less than 0.15 per cent and not more than 0.20 per cent of the final product. The preparation also contains approximately 1.6 per cent of glycerin as an agent for achieving of isotonicity, and 0.20 per cent of cresol or 0.25 per cent of phenol as a preservative.

**Actions and Uses.**—The effects of protamine zinc insulin are as described under Insulin-N. N. R., except that the blood-sugar-lowering action of unmodified insulin becomes maximal in from two to three hours, whereas the blood-sugar-lowering action of protamine zinc insulin is prolonged and has its greatest effect in about twelve to twenty-four hours after administration.

Protamine zinc insulin may be used in the case of any patient where regulation of diet is incapable of removing the cardinal objective symptoms of diabetes mellitus, and may replace, wholly or partly, the use of unmodified insulin in the treatment of the patient. In some cases the use of unmodified insulin alone is desirable; in others, protamine zinc insulin alone is indicated; while in others, the use of both preparations gives best results.

In view of the prolonged action of protamine zinc insulin, the chief indications for its use are in those cases where unmodified insulin is unable to provide control, without being administered in several doses daily, or is unable to provide adequate control unaccompanied by frequent hypoglycemic reactions, ketosis, or evidence of pronounced fluctuations in blood sugar levels. The usefulness of protamine zinc insulin in cases of diabetic coma, in diabetes complicated by infection, or in the event of surgical operations has not been definitely established. In such instances, therefore, the use of protamine zinc insulin to supplant the use of unmodified insulin is not recommended.

**Dosage.**—The general principles underlying the administration of protamine zinc insulin are the same as those governing the administration of unmodified insulin (see Insulin-N. N. R.).

Protamine zinc insulin is to be injected *only subcutaneously*. In most cases its administration more often than once a day is not required. The initial dose should be from about two-thirds to equal the number of units that would be needed daily to maintain the patient "sugar free" under treatment with unmodified insulin. In some instances glycosuria may follow owing to the slow absorption and consequent delayed action of protamine zinc insulin. Hence on the first few days when protamine zinc insulin is being used, it may be advantageous to administer a separate dose of unmodified insulin. It is usually possible to discontinue the use of unmodified insulin after the first or second day, though in some instances the administration of both preparations requires to be continued indefinitely.

Protamine zinc insulin is generally administered either in the morning (from one-half to one and one-half hours before breakfast), or in the evening (one hour before supper or one hour before retiring). Diet must be adjusted with the prolonged blood-sugar-lowering effect of the product in mind, and a redistribution of food among individual meals is usually desirable. In particular, the carbohydrate content of the meal following the injection of protamine zinc insulin may require to be limited in order to avoid hyperglycemia. The carbohydrate of the diet not included in this meal is divided between the other meals of the day in such a manner as to prevent hypoglycemia at times when the dose of protamine zinc insulin is exerting its greatest effect.

Symptoms of hypoglycemic reactions following administration of protamine zinc insulin are similar to but may be less obvious than those following injection of unmodified insulin, and may consist merely of a feeling of pronounced fatigue unwarranted by the activities of the patient. When a hypoglycemic reaction is occasioned by protamine zinc insulin, the reaction may be prolonged, and despite its having been treated, it may repeat itself owing to the continuing effect of the dose administered. It is therefore advisable to use both a soluble and a more slowly digestible carbohydrate in treating such reactions, for example, corn syrup with bread or bread with honey. Alternatively, and even though the patient may appear to be restored to normal through use of a soluble carbohydrate food such as orange juice, it is advisable to provide additional carbohydrate after the lapse of one or two hours. Soda biscuits and milk are suitable at that time. In severe reactions, it may be desirable to inject from 15 to 20 Gm. of dextrose in sterile solution intravenously, followed later by food.

In protamine zinc insulin, the insulin component is derived from batches previously tested and approved in their unmodified form; the protamine component is derived from sperm or mature testes of fish belonging to the family Salmonidae, genus *Oncorhynchus*, *Salmo* or *Trutta*; and the zinc component is derived from a solution of zinc chloride (0.17 mg. of  $ZnCl_2$  provides 0.08 mg. of zinc). Protamines are basic proteins of simple composition. These substances are prepared according to methods described by Kossel. (Kossel, A.: *The Protamines and Histones*, in *Monographs on Biochemistry*, translated by W. U. Thorpe, 1928 ed., pp. 18-19).

Protamine zinc insulin is supplied in vials. The filling of each vial includes two distinct operations in that an accurately measured aprotic quantity of a sterile acidic solution (insulin, protamine and zinc) is placed in the vial, followed, separately, by an accurately measured, appropriate quantity of a sterile alkaline solution (buffer).

The resultant product is a suspension of finely divided particles. Each filling of protamine zinc insulin is subjected to sterility tests as prescribed for turbid or precipitated biological products intended to be used parenterally. A sample of each batch of the product is tested by comparison with a sample of some other batch of the product that has proved satisfactory in laboratory and clinical trial. The sample under test is considered satisfactory only if, upon comparison by suitable methods of biological assay, its effects are shown to be essentially the same as the effects given by the other sample.

To estimate its zinc content, transfer about 1 cc. accurately measured, of the well mixed protamine zinc insulin to a 25 cc. platinum dish, add 0.3 cc. of 1:1 mixture of sulfuric acid and water; evaporate and ignite residue slowly (begin with the muffle door open, then increase the heat to around 650° with the door closed). After cooling, add 15 cc. of water and 7 cc. of 3 normal hydrochloric acid. Evaporate the solution to one-half volume on the steam bath and filter into a 50 cc. Erlenmeyer flask. Wash the residue until the

diately before or during the illness. Abdominal pain was a symptom in twelve instances. The pain was located in the epigastrium in four children, in the left lower quadrant in one, and generalized in the other seven. Localized abdominal tenderness was not elicited by palpation in any patient. It is important to note that abdominal tenderness was the outstanding symptom in the epidemic of pleurodynia occurring in this city at

Chart 1.—Composite chart of daily temperature readings of the entire group.

the same time.<sup>8</sup> However, in the patients with the latter disease the pain was located characteristically along the costal margin and their cerebrospinal fluids were normal. Drowsiness was noted in less than half of the group of patients but it never was a marked symptom and no child lapsed into coma or delirium. Convulsions, diarrhea or constipation did not occur in any patient.

**Physical Examination.**—The usual conditions found were stiffness of the neck and positive Kernig and Brudzinski signs. One or more of these tests was positive in all but one child and all three signs were present in five children. In the one instance in which none of these tests were elicited the symptoms of vomiting and headache led to the suspicion of the illness, and the contents of the cerebrospinal fluid confirmed the diagnosis. In other respects the neurologic examination of these patients was negative except for the finding of a ptosis of the eyelids in one child and a weakness of the facial muscles on one side in another. Since these changes were noted during the initial examination and the parents had not noticed any change in the children's facial expression, it was questionable in each case whether such lesions were recent or had been present before the onset of the illness.

**Fever.**—The highest temperatures were 104 F. on admission to the hospital. Defervescence was rapid and complete by the end of seven days except in the instance of one patient who had a secondary rise of temperature on the ninth day as the result of a serum reaction. This patient had received antimeningococcus serum because of the suspicion that the illness was due to the meningococcus. The majority of patients were sick only one to three days before admission to the hospital and never more than seven days, so the duration of the fever may be said to be two weeks; while in the majority of patients fever lasted only about one week. Chart 1 indicates the composite picture of the duration of fever.

**Blood Leukocytes** (chart 2).—The total number of leukocytes in the blood ranged between 7 and 18 thousand per cubic millimeter with ten children of the group (45 per cent) having less than 10 thousand. In fourteen (64 per cent) the proportion of polymorphonuclear neutrophils was increased above normal. In only one patient did the lymphocytes constitute more than 50 per cent of the total number of cells.

**Cerebrospinal Fluid** (table 3).—The fluid was generally clear, the globulin content was increased above normal in about half the number of patients and the number of cells present was from 50 to 200 in the majority of instances but reached as high as 1,100. The cell counts dropped to 10 or less within one to three weeks after the onset of the illness, and the cerebrospinal fluids of two patients examined more than a month later were normal. Lymphocytes were the predominant cells. In five patients the initial differential count showed a predominance of the polymorphonuclear neutrophils, but after a few days the lymphocytes were more numerous. In the early part of the epidemic a few patients were referred to the hospital with the diagnosis of probable meningococcic meningitis and were treated with specific antiserum before the cerebrospinal fluid could be examined. Subsequent cell counts of the cerebrospinal fluid of these patients, of course, showed a reaction to the serum but these results were not included in the table. Examinations and cultures of the fluids in nutrient blood agar, dextrose ascites agar and brain broth<sup>9</sup> were negative for microorganisms in every instance.

Dr. T. F. McNair Scott of the Rockefeller Institute examined the blood serums of three patients for anti-

Chart 2.—Total number of leukocytes and the differential counts.

bodies of the virus isolated by Dr. Rivers and himself.<sup>6</sup> The serums were collected about seven months after the patients had recovered from their illnesses and the specimens of two patients showed a weakly positive neutralizing power against the virus. The serum of the third patient was negative.

## SURGICAL TREATMENT OF MALIGNANT HYPERTENSION

In his classic monograph "Ueber den Zusammenhang von Herz und Nierenkrankheiten," Traube postulated in 1856 the compensatory theory of the development of elevated arterial pressure in diseases of the kidneys. He considered the elevation of the arterial pressure an effort on the part of the organism to overcome the mechanical resistance against blood flow and an effort to maintain the excretory function of the kidneys. With the introduction of accurate measurement of the blood pressure, hypertension was found to be one of the most frequent complications of renal disease. The conclusion was drawn that renal influences in some way contributed to the hypertension.

In an attempt to determine the nature of renal influence in hypertension, Page and Heuer<sup>1</sup> performed bilateral renal denervation on a patient suffering from essential hypertension uncomplicated by recognizable renal involvement and with but slight evidence of anatomic changes in the circulatory system. The level of the arterial blood pressure remained unchanged. The renal efficiency, as measured by the urea clearance test and the ability of the kidneys to concentrate, remained unchanged. They concluded that renal denervation is not effective in treatment of essential hypertension and that the hypertension does not originate in the nervous mechanism of the kidneys. Page<sup>2</sup> showed in clinical studies of cases of malignant hypertension, in cases of moderate hypertension and in cases with hemorrhagic nephritis that the efficiency of the kidneys, as measured by the urea clearance test, is not altered by a fall in the arterial blood pressure occurring spontaneously or induced by sodium thiocyanate administered by mouth. Neither was it controlled by colloidal sulfur administered intramuscularly in patients suffering from essential hypertension. He concluded that the abnormal elevation of blood pressure in these cases does not

appear to assist in the maintenance of renal efficiency. This evidence does not support the compensatory theory of the cause of hypertension in patients suffering from nephritis or from essential hypertension.

The newest experimental procedure in hypertension is sympathectomy. Leriche demonstrated in extensive clinical material that vasodilatation can be produced and maintained by arterial sympathectomy. Brünig in 1923 suggested sympathectomy for control of hypertension. Adson and Brown<sup>3</sup> demonstrated that sympathetic ganglionectomy and trunk resection produce an increased blood flow, as measured in degrees of increased elimination of heat. They also found that following cervico-thoracic ganglionectomy the caliber of retinal arteries and veins, as determined by the ophthalmoscopic micrometer, has been increased from a third to a half of the preoperative size. In their attempt to alter the vasomotor control of arteries below the diaphragm, the authors conceived the idea of sectioning the anterior spinal roots bilaterally from the sixth thoracic to the second lumbar, inclusive. The effect of this procedure would be to interrupt the thoracolumbar sympathetic outflow below the fifth thoracic segment and to paralyze the abdominal muscles. The authors hoped by this procedure to sympathectomize sufficient arteries to modify arterial responses, to sympathectomize thoroughly the suprarenal glands and to remove the effects of intra-abdominal pressure. They obtained a favorable result in a severe case of hypertension and felt that better results could be accomplished in younger patients with more flexible vascular systems. Page and Heuer<sup>4</sup> performed the same operation on a girl with a high arterial blood pressure but with a still flexible vascular system. The blood pressure level fell quickly to normal and has remained normal for seven months.

Freyberg and Peet<sup>5</sup> now report forty-eight cases in which the operation of splanchnicectomy, as devised by Peet, was carried out. The operation consists of a bilateral sectioning of the major and minor splanchnic nerves and of the lower dorsal sympathetic chain, including the tenth, eleventh and twelfth ganglions, supradiaphragmatically. In almost every case there was a sharp fall in blood pressure to normal or below immediately after the operation. The result was permanent in some and less permanent in others, while the blood pressure rose to the preoperative level in still others. The authors stress the fact that splanchnicectomy performed on patients with primary hypertension does not interfere with the functional efficiency of the kidneys, as measured by concentration and urea clearance tests, whether or not significant decrease in blood pressure results. When hypertension is greatly relieved by the

## Clinical Notes, Suggestions and New Instruments

### AGRANULOCYTOSIS ASSOCIATED WITH THE ADMINISTRATION OF "NOVALDIN," A DERIVATIVE OF AMINOPYRINE

THEODORE G. KLUMPP, M.D., NEW HAVEN, CONN.

That aminopyrine is capable of causing agranulocytosis is now generally recognized. There is ample evidence that because of this danger informed physicians have either wisely stopped prescribing aminopyrine or are using it with the utmost care. In Denmark, where the medical profession has been induced to refrain from the prescription of the drug, not a single case of angina agranulocytica has occurred.<sup>1</sup>

On the other hand, most physicians are not organic chemists and when confronted with "Novaldin, Brand of Dipyrone (Sodium phenyldimethylpyrazolon methylaminomethane sulphate),"<sup>2</sup> cannot be expected to know that it is a derivative of aminopyrine and contains the chemical radical that has been etiologically related to agranulocytosis. "Novaldin" is in fact aminopyrine with the substitution of the sodium salt of methyl sulfonic acid for one of the methyl groups attached to the amino nitrogen. This simple chemical maneuver, called "sulfonation," is commonly employed to increase the solubility of a compound without materially altering its chemical and pharmacologic properties. The essential similarity of aminopyrine and "Novaldin" is evident from the structural formulas:

Theoretically "Novaldin" should share with aminopyrine the potentiality of causing agranulocytosis. That this is true is suggested by the experiment of Benjamin and Biederman.<sup>3</sup> These authors administered 10 grains (0.6 Gm.) of "Novaldin" to a volunteer who had had several attacks of agranulocytic leukopenia due to aminopyrine and were able to produce a prompt neutrophilic leukopenia accompanied by malaise, headache, backache and slight pyrexia.

In the following report the occurrence of a fatal case of agranulocytosis associated with the administration of "Novaldin" is recorded, with autopsy.

#### REPORT OF CASE

**History.**—N. A. B., a white man, aged 43, married, Swiss-American, an inspection engineer, was admitted to the New Haven Hospital, Jan. 28, 1935, at 4 p. m., because of difficulty in breathing.

For approximately twenty years the patient had been troubled with minor digestive disturbances and frontal headaches associated with emotional upsets, anxiety or eyestrain. Otherwise he had been in good health.

Five months before admission the patient consulted his physician because of headaches. The physician warned him against aminopyrine, because of the danger of agranulocytosis, and prescribed instead "Novaldin." The patient took this drug every day, with occasional omissions. The exact dosage taken, however, is not known. In December 1934 phenobarbital, one-third grain (0.02 Gm.) three times a day, was prescribed for the patient's minor digestive disturbance.

From the Department of Internal Medicine of Yale University School of Medicine and the New Haven Hospital.

3. Benjamin, J. E., and Biederman, J. B.: Agranulocytic Leukopenia Induced by a Drug Related to Aminopyrine, J. A. M. A. 107: 493-494 (Aug. 15) 1936.

January 23, five days before admission, the patient was exposed to the cold during a six hour automobile trip. On his return home he felt chilly, unusually fatigued, and went directly to bed. The next day he continued to feel chilly and developed a headache, which persisted throughout the illness. After an alcoholic drink he returned to bed. During the night he perspired profusely. The following day, three days before admission, his throat felt sore, his tonsils seemed swollen, and a temperature of 102 F. by mouth was recorded. His condition grew rapidly worse and a physician was called, who swabbed his throat with a 3 per cent solution of silver nitrate and prescribed a gargle containing potassium chlorate and ferric chloride and morphine one-eighth grain (0.008 Gm.). The patient also took a number of acetylsalicylic acid tablets.

The day before admission slight jaundice and rapidly increasing obstruction to breathing appeared. Cyanosis developed and on the day of admission it was feared that he would choke to death. Hospitalization was ordered.

**Physical Examination.**—On admission the body temperature was 104.5 F., pulse 143, respiration 40, and blood pressure 130 systolic, 80 diastolic. The patient was desperately ill, perspiring freely, restless, apprehensive and quite unable to talk. Inspiratory stridor, cyanosis and dyspnea were pronounced. The accessory muscles of respiration were brought into play. The breath had a foul, gangrenous odor. The tonsils and oral pharynx were inflamed and boggy and showed ulcerative necrotic lesions covered with a firmly adherent, dirty, grayish black membrane. When this was removed in part, it left an ulcerated surface with many bleeding points. Except for inflammation and edema, the uvula, soft palate and anterior pillars were not conspicuously involved. The soft tissues of the neck were edematous and the tonsillar and anterior cervical lymph nodes were greatly enlarged. No abnormalities were discovered on examination of the lungs. Except for tachycardia, the heart appeared normal. The liver edge was felt 2 cm. below the costal margin. The spleen could not be felt.

**Laboratory Examination.**—Blood studies were as follows: red blood cells 5.0 million; hemoglobin 90 per cent of 15.4 Gm.; white blood cells 150. On examination of the smear only 20 leukocytes were seen, of which 2 were monocytes and the remainder lymphocytes. These cells did not appear abnormal. The red blood cells and platelets were normal in number and appearance. Fluctuations in the number of leukocytes are given in the table.

#### Fluctuation in Number of Leukocytes

Leukocytes		Differential Count
1/23 4:00 p. m.	150.....	20 cells: 18 lymphocytes, 2 monocytes
9:00 p. m.	230.....	10 lymphocytes
10:00 p. m.	Transfusion 500 cc.	
11:30 p. m.	100.....	4 lymphocytes
1/23 8:30 a. m.	450.....	No neutrophils seen
11:00 a. m.	Liver extract from 500 Gm. of liver	
12:00 noon	Transfusion 500 cc. blood	
1:30 p. m.	1,950.....	10 lymphocytes, 2 monocytes
3:00 p. m.	600.....	7 lymphocytes, 2 monocytes

The urine was deep amber, acid, had a specific gravity of 1.018, albumin 4+, sugar 0, bile 2+, no sediment, and the Kahn test was negative. The icteric index was 100. Blood non-protein nitrogen was 81 mg. per hundred cubic centimeters. Throat cultures revealed nonhemolytic streptococci +, Staphylococcus aureus +, diphtheria bacilli 0. Blood cultures revealed Streptococcus viridans +, a gram-negative bacillus, probably B. coli, +. The direct smear from the throat was chiefly remarkable for its complete absence of leukocytes.

**Clinical Course and Treatment.**—On admission to the hospital, the patient was immediately placed in a steam room and kept there for three hours. Because of his critical condition and the possibility of fulminating diphtheria, which could not be definitely dismissed at this time, 20,000 units of diphtheria antitoxin was given intravenously and 40,000 intramuscularly shortly after admission. One hour after entry into the hospital 1,500 cc. of saline solution and 100 cc. of 5 per cent dex-

zinc sulfate solution has a better effect and is more satisfactory than the picric acid-alum solution; this evidence has been developed wholly on monkeys, and human experiments are not yet available to prove the efficacy of the zinc sulfate method in the human being. In his conclusion DeKruif recommends that physicians apply the zinc sulfate prevention method on a large scale wherever epidemics threaten next year and that health departments everywhere organize for the purpose. Time will no doubt show whether or not the method is as good as DeKruif seems to think it is.

The series of publications and educational activities associated with the periodical *Time* are devoting themselves in a serious manner to aiding the campaign against cancer. The current issue of the talking motion picture *March of Time* presents a lecture and a series of pictures which have received favorable comment from the medical profession wherever they have been shown. They would seem to be invaluable in educating the public regarding the nature of research against cancer, regarding the use of radium, the x-rays and surgery, and regarding the menace of cancer quackery. Advance reports indicate a special article on cancer which will appear in the March issue of *Fortune* magazine, and a photographic educational series which will appear in an early issue of *Life*. Already the *March of Time* broadcast on the radio has reflected to the public the new campaign against cancer. The headquarters of the Association has cooperated in these productions. This type of cooperation in the education of the public is important for the medical profession, and the publications concerned are hereby tendered the thanks of THE JOURNAL for the manner in which the work has been carried on.

A considerable contrast to the efforts previously described is the utter folly represented by the series of articles now being published in the *Cosmopolitan* magazine under the authorship of Rex Beach, who has promoted two foot manipulators, a cataract charlatan, a dietary quack and other exploiters of strange notions in the field of health and healing. Conspicuous also are the trumpery, charlatanism and pure silliness involved in such medical articles as have been published from time to time in *Esquire* and which are more recently being published in *Coronet*. It is inconceivable that either the publisher or the editor of these periodicals has even a reasonably competent understanding of the articles that are being published and certainly it is inconceivable that any competent physician is advising them. The promotion of Duncan and his system of autotherapy was, of course, utterly without any scientific warrant and disgusting besides.

The most recent explosion in relationship to medical economics was in the *Literary Digest* for January 30. The article seemed to average one or two errors of fact in every few paragraphs, varying from its exaggeration of the number of physicians on relief to one relative to the membership of the American Medical

Association. The article stated that at one time there were 400 physicians on relief in Chicago, whereas it is doubtful that the number ever exceeded seven. Indeed, Harry Hopkins himself stated that the number for the whole country was approximately 675 physicians on relief. The article stated that the American Medical Association had 120,000 members, whereas it boasts of 104,000 members out of approximately 130,000 practicing physicians and 165,000 licensed physicians in the country. A complete statement has been sent to the *Literary Digest* relative to the disputed points in this article, and the editors of that periodical promise an extended consideration of the subject in a future issue.

## Current Comment

### PROTAMINE AND INSULIN PREPARATIONS

From its introduction fourteen years ago, insulin underwent relatively little modification until Hagedorn<sup>1</sup> and others of Denmark showed that the blood-sugar-lowering action of insulin was prolonged when it was combined with protamine.<sup>2</sup> The product was first called "Protamine Insulinate," "Insulin Protamine," or "Insulin Protamine Compound." Later the generally accepted term was Protamine Insulin. Following the announcement of Hagedorn's results, much experimental work was undertaken. Scott and Fisher,<sup>3</sup> working at the University of Toronto, found that the addition of a zinc salt to a protamine and insulin mixture enhanced the prolongation effect of insulin in diabetic patients. Until recently the product given to investigators for clinical trials consisted of two vials. The contents were mixed by the physician before use. Various investigators in collaboration with the University of Toronto group have aided in the development of a pharmaceutically improved product of insulin, modified by the presence of protamine and zinc, which may be dispensed in a single vial. This product has now been designated "Protamine Zinc Insulin." Elsewhere in this issue appears a description of Protamine Zinc Insulin, now being manufactured under license by a number of pharmaceutical concerns. Physicians should read the epitomized description of the product and its actions, uses and dosage.<sup>4</sup> Protamine Zinc Insulin does not replace insulin (unmodified) in all cases or under all circumstances. Protamine Zinc Insulin may be used alone or used concurrently with the administration of unmodified insulin; or in some cases unmodified insulin may be used to advantage without employing Protamine Zinc Insulin. The choice of technic of administration depends on such factors as the diet of the patient, exercise, and pathologic complications. Further clinical experience may indicate certain limitations and advantages not yet recognized, and undoubtedly advances in the manufacture of this

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION  
OF THE FOLLOWING REPORTS.      HOWARD A. CARTER, Secretary.

PEERLESS ULTRA SHORT WAVE  
GENERATOR, MODEL UW2-A,  
ACCEPTABLE

Manufacturer: Peerless Laboratories, Inc., New York.

The Peerless Ultra Short Wave Generator, Model UW2-A, is recommended for medical and surgical diathermy. It is a two-tube machine with a fixed wavelength of about 6 meters. The patient's circuit is inductively and capacitively coupled to the oscillator circuit for medical and surgical diathermy.

Tuning of the patient's circuit is accomplished with a double condenser. Electric field electrodes of various sizes are provided as regular equipment. Evidence for the air-spaced electrodes and induction coil was not submitted. Only the cuff electrodes are considered herein.

For consistency of performance and maximum life to tubes and other component parts, a switching arrangement is incorporated in the machine which enables the physician to adjust the operating voltages on filament, grid and plate to line voltage variation within a range of from 105 to 135 volts in the power supply line.

When this machine is operated under full load it draws from the alternating current supply line not more than 1,200 watts. Since no reliable method has been proposed to measure the output energy available to the patient, the value is not given.

Averages of Eight Observations with Cuff Electrodes

Intramuscular Temp. F.		Subcutaneous Temp. F.		Rectal Temp. F.	
Initial	Final	Initial	Final	Initial	Final
97.0	105.5	93.2	103.5	99.4	99.7

The firm was asked to obtain evidence from a reliable investigator to substantiate the claims made for the unit. Using human subjects, the heating effect of the tissues in the thigh was observed. The cuff electrode method of application was investigated. Four vigorous men ranging in age from 23 to 35 years were obtained for the experiments. Temperature measurements were observed by means of thermocouples of the hypodermic type, before and after a twenty minute treatment. The temperature measurements were read on a potentiometer. Thermocouples were calibrated by a standard thermometer in degrees Fahrenheit. The intensity of the diathermy current was governed by the patient's skin comfort. Rectal temperatures were also observed. Cuff electrodes of size 3.8 by 37.5 cm.

were wrapped around the thigh, one electrode at the proximal thigh and the other at the distal. The distance from center to center of the cuff electrodes was 2.3 cm. and the spacing of felt and toweling between the leg and cuff was about 2.5 cm.

Two observations were made on each patient, one on the right thigh and the other on the left, making a total of eight observations. The depth of insertion of the point of the thermocouple was approximately 2 inches, or until the femur was encountered. The subcutaneous temperature was taken at a depth of about one-eighth inch below the skin surface. Anesthetics were not used prior to insertion of the thermocouple.

Each item given in the accompanying table is an average of eight observations, application by cuff electrodes.

The results indicate that the temperature rise with the aforementioned method of application is considerably above what can be expected in the application of conventional diathermy—with a metal electrode on the medial aspect of the thigh and another metal electrode on the lateral aspect—the method of application that has been adopted as a minimum standard of acceptance.<sup>1</sup>

The temperature rise of the transformer, after the machine had been operated at full load for two hours, came within the limits of safety prescribed by the Council. The shipping weight of the apparatus is about 150 pounds. Burns may be produced but may be avoided by ordinary precaution. Their likelihood to occur is less than with conventional diathermy, employing metal electrodes.

The machine was used in a clinic acceptable to the Council and was operated under actual clinical conditions. It was reported as giving satisfactory service. In view of the favorable report based on the performance of this unit when employing cuff electrodes, the Council on Physical Therapy voted to include the Peerless Ultra Short Wave Generator, Model UW2-A, in its list of accepted devices.

EMERSON SUCTION PRESSURE APPARATUS  
ACCEPTABLE

(For Treating Peripheral Vascular Diseases)

Manufacturer: J. H. Emerson, Cambridge, Mass.

This apparatus is recommended by the firm for the treatment of peripheral vascular diseases of the extremities by alternating positive and negative pressure.

Essentially, the apparatus consists of an air compressor and vacuum pump, a "boot" or chamber in which the patient's limb is confined. The boot is of noninflammable celluloid and weighs 15 pounds. The cuffs are made of molded solid rubber and there are a number of smaller cylinders telescoping inside one another. In addition to the regular adjustments to set the amount of positive and negative pressures, there is an adjustment provided for altering the duration of the cycle of pressure change between ten and sixty seconds, and an adjustment for varying the time ratio of positive to negative pressure. The compressor is compact and movable and the shipping weight of the combined apparatus is about 200 pounds.

The apparatus was investigated in a clinic acceptable to the Council, and the investigator reported that the unit was capable of increasing collateral circulation.

The types of cases benefited by this type of apparatus appear to be acute vascular occlusion, frost-bite, and vascular diseases with major involvement of the large vessels. The contraindications appear to be thrombophlebitis, cellulitis or lymphangitis (acute or subacute), extensive destruction of the arteriolar or capillary vessels, advanced thrombo-angiitis obliterans with capillary stasis, and advanced arteriolar sclerosis with capillary stasis, and venous thrombosis.

1. Mortimer, Bernard, and Osborne, S. L.: Tissue Heating by Short Wave Diathermy, J. A. M. A. 104: 1413 (April 20) 1935.

in the business of insurance against the need for medical and hospital services and to regulate the manner in which such business is conducted. The bill states that it "is intended to govern all contracts between physicians and surgeons and other persons, which provide that for certain regular sums, or for a stated sum for a stipulated period the physician and surgeon or association of physicians and surgeons will furnish to the other person all medical and surgical services, including hospitalization and nursing, which may be required by such person, irrespective of the actual value of the services furnished." A. 1721 proposes to prohibit the retail sale or other retail distribution of contraceptives and any devices, appliances, or medicinal agents used in the prevention of venereal disease, except by a licensed pharmacist or by a licensed physician or licensed osteopath. A. 1783, to supplement the business and professions code, by the addition of a section 114 to that code, proposes to authorize courts to enjoin (1) the unlicensed practice of any profession or vocation and (2) a licentiate from committing any act the doing of which constitutes a cause for revocation or constitutes unprofessional conduct. A. 1472 proposes to establish a board of naturopathic examiners and to regulate the practice of naturopathy. The bill proposes to define naturopathy as "diagnosis of all human ailments and abnormalities and the practice of physiological and mechanical sciences such as mechano-therapy, electro-therapy, physio-therapy, articular manipulation, hydrotherapy, mineral baths and dietetics, which shall include the use of foods of such chemical tissue-building products and cell salts as are found in the normal body; and the use of oils, dehydrated and pulverized fruits, seeds, barks, non-narcotic herbs, roots and vegetables." A. 1196 proposes to permit the governing authorities of city, county, or city and county hospitals to admit and care for nonindigent patients and to establish rates or fees to be charged such non-indigent patients for services rendered and supplies furnished. S. 781 and S. 783 propose to authorize courts to restrain the unlicensed practice of medicine or of osteopathy. A. 2029, to amend the workmen's compensation act, proposes to make silicosis, asbestosis and pneumoconiosis compensable under certain conditions. A. 1880 proposes to authorize city and county boards of education to grant health and development certificates to "physicians and surgeons holding certificates issued by the California state board of osteopathic examiners." The present law permits the issuance of such certificates only to holders of certificates to practice medicine and surgery issued by the board of medical examiners. S. 731, to amend the medical practice act, proposes to include as unprofessional conduct, which is a cause for the revocation of a license, "advertising or holding out to the public that professional services of a specified nature will be rendered for a particular, definite or fixed price." A. 2011, to amend the workmen's compensation act, proposes to permit an injured worker to "select any person licensed to render the type of treatment or service required." A. 1320, to amend the medical practice act, proposes to designate as unprofessional conduct, which is a ground for revoking a license, "the actual practicing of any system or mode of treating the sick or afflicted which is intended or has a tendency to deceive the public or impose upon credulous or ignorant persons, and so be harmful or injurious to public moral[s] or safety." A. 1333 proposes to prohibit the manufacture, or sale or offering for sale of any adulterated, mislabeled or misbranded cosmetics. The term cosmetic is to apply to all "substances and preparations intended for external or oral use in cleansing, or altering the appearance of, or promoting the attractiveness of, the person." A cosmetic will be deemed adulterated if its standard of purity, strength or quality fall below the standards provided by the state board of health or if its purity, strength or quality fall below the professed standard of purity, strength or quality under which it is sold or if it contains any poisonous or deleterious substance in such quantity as may render it injurious to the user under the conditions of use prescribed in the labeling thereof, or under such conditions of use as are customary or usual. A cosmetic will be deemed mislabeled or misbranded if its package or label bears any statement which is false or misleading in any particular whatsoever or if the efficacy of the article or its ingredients are falsely or deceptively advertised. A. 1253, to amend the act prohibiting the manufacture, sale or transportation of adulterated, mislabeled or misbranded drugs, proposes to define "drug" so as to include (1) devices intended to be used for the cure, mitigation or prevention of disease and (2) all chemicals or substances of whatever nature used in the treatment of obesity. The bill proposes that the standard of purity of drugs not listed in the United States Pharmacopeia or in the National Formulary shall be the standard of strength, quality or purity established by the state board of health. A drug is to be deemed to be mislabeled or misbranded if adver-

tising matter used in connection with its sale contains any statement regarding its curative or therapeutic effect that is false and fraudulent. The bill further proposes to prohibit the advertisement of drugs, treatments or cures for venereal diseases, impotence, self abuse, cancer, tuberculosis, diabetes or heart trouble, except such advertisements as are disseminated to the medical and pharmaceutical professions. A. 1089 proposes to require the state board of health to establish and maintain a bureau of venereal diseases to cooperate with physicians and surgeons, medical schools, hospitals, dispensaries, clinics, schools, penal and charitable institutions, local health officers and boards, and federal health authorities in the control, prevention and cure of venereal diseases.

## COLORADO

**Bill Introduced.**—H. 364, to amend the law prohibiting the production, manufacture, possession or distribution of marihuana, proposes to make a violation of the provisions of the act punishable by imprisonment in the state penitentiary for not less than one nor more than ten years.

**Annual Registration Due Before March 1.**—Every person licensed to practice any form of the healing art in Colorado is required by law to register annually before March 1, with the secretary-treasurer of the Board of Medical Examiners, and to pay a fee of \$2, if a resident of Colorado, or \$10, if a nonresident. Failure to pay this fee within the time stated automatically suspends the right of a licentiate to practice while delinquent. If he nevertheless continues to practice, he is subject to the penalties provided by law for practicing medicine without a license. Failure to pay this fee for three consecutive years results in the automatic cancellation of a delinquent practitioner's license to practice.

**Dr. Hall Honored.**—Dr. Josiah N. Hall, professor of medicine, emeritus, University of Colorado School of Medicine, Denver, will be guest of honor at a testimonial dinner given February 20 by Dr. Hubert Work, formerly Secretary of the Interior. Dr. Hall has recently announced that he will retire from active practice March 1. He is 77 years of age. A native of Chelsea, Mass., Dr. Hall graduated from Harvard University Medical School in 1882. The following year he began practice in Sterling, remaining there until 1892. He has been in Denver since that time. He was major and surgeon in the medical reserve corps of the U. S. Army in 1917, and chief of medical service, Base Hospital, Camp Logan, Texas. Later he served as consultant in internal medicine to the sixteen southwestern military hospitals during the war. Organizations of which he has been president include the Colorado State Board of Medical Examiners, 1891; the state board of health, 1903-1904; state medical society, 1900, and the American Therapeutic Society, 1916-1917. He was mayor of Sterling, 1888-1889. He served on the Judicial Council of the American Medical Association from 1921 to 1931 and was a member of the House of Delegates at various times from 1903 to 1921. He wrote the section on Gun-Shot Wounds, Burns and Scalds in Peterson and Haines' A Text-Book of Legal Medicine and Toxicology, 1903, and is the author of *Borderline Diseases*, 1915. In 1933 the Medical Society of the City and County of Denver held a dinner to observe his completion of fifty years in the practice of medicine in Colorado. Tribute was paid to Dr. Hall in 1936 at the annual meeting of the state medical society when the banquet and president's reception was dedicated to him in recognition of his fiftieth year of attendance at the annual sessions of the society.

## CONNECTICUT

**Bills Introduced.**—S. 425 and H. 629, to amend the law regulating the conduct of maternity hospitals, proposes that such hospitals be licensed by the state department of health rather than by the appropriate local health officer, as the present law provides. S. 419 proposes to appropriate \$100,000 to the state department of health to be used for the treatment of indigent typhoid and paratyphoid germ carriers. S. 373 proposes to require the governor to appoint a commission, to consist of five members, to investigate the subject of social health insurance and to report its findings, with recommendations for legislation, to the next session of the general assembly. H. 773 and S. 565, to amend the workmen's compensation act, propose to limit the liability of an employer to furnish "medical and surgical aid or hospital service" to an injured employee to the first sixty days after an industrial injury. S. 800 proposes to add \$2 to each annual motor vehicle registration fee to create a state fund with which to pay for medical expenses rendered to indigent residents of Connecticut injured in a motor vehicle accident occurring on the highways of the state. S. 1027 proposes that in the distribution of a decedent's estate the claims of

volume of the filtrate is approximately 25 cc., add 3 drops of solution of bromophenol blue, followed by stronger ammonia water until the solution assumes a blue color, then add just enough hydrochloric acid to make the solution slightly yellow. Add approximately 5 cc. of sodium citrate buffer (12 Gm. sodium citrate, 23 Gm. citric acid in 100 cc. water) and adjust the entire mixture to a  $pH = 3.0$ . The solution should now have a gray color—neither yellow nor blue. Warm the solution on a steam bath and rapidly pass in hydrogen sulfide for two minutes. (Iron may be reduced in slightly acid solution by using a little  $SO_2$ ). Add 0.05 Gm. of acid and alkali washed talcum. Filter the solution through a Whatman filter No. 1 (7 cm.), wash with 10 cc. hydrogen sulfide saturated water containing 5 cc. of 90 per cent formic acid in 1 liter. After the filter is dry, elute the zinc with approximately 15 cc. 1 normal hydrochloric acid and transfer into a flat bottom Nessler tube. Add 2 cc. of 5 normal sodium hydroxide and fill up to 20 cc. Add 2 drops of 2 per cent potassium ferrocyanide, and compare with standards containing 0.05 mg. to 0.1 mg. zinc (nephelometrically): One cc. of protamine zinc insulin containing 40 units per 1 cc. should yield the equivalent of not less than 0.07 mg., nor more than 0.10 mg. of zinc. The zinc standard is made by dissolving 1 Gm. of pure zinc in concentrated hydrochloric acid, diluting it to 1 liter.

Patents and trademarks—See Insulin, N. N. R. Additional patents applied for.

**Protamine, Zinc & Iletin (Insulin, Lilly).**—A brand of protamine zinc insulin.

Manufactured by Eli Lilly and Company, Indianapolis, under license from the governors of the University of Toronto.

**Protamine, Zinc & Iletin (Insulin, Lilly), 10 cc.:** Each cubic centimeter contains 40 units of insulin, together with protamine and approximately 0.08 mg. of zinc.

**Protamine Zinc Insulin.—Squibb.**—A brand of protamine zinc insulin.

Manufactured by E. R. Squibb & Sons, New York, under license from the governors of the University of Toronto.

**Protamine Zinc Insulin.—Squibb, 10 cc.:** Each cubic centimeter contains 40 units of insulin together with protamine and approximately 0.08 mg. of zinc.

## REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.  
PAUL NICHOLAS LEECH, Secretary.

### ICHTHYOL READMITTED TO N. N. R.

Ichthyol, marketed by Merck & Co., Inc., Rahway, N. J., was included in New and Nonofficial Remedies until 1924. It was omitted because unwarranted claims were made for the product, as explained in a report published in THE JOURNAL (Feb. 16, 1924, p. 565). Merck & Co., Inc., requested reconsideration of Ichthyol in 1935 and has revised its advertising claims to conform with the Council's views as to the action and uses which are expressed in the article "Sulphoichthyolate Preparations and Substitutes," New and Nonofficial Remedies, 1936. Accordingly, the Council has reaccepted Ichthyol for inclusion in New and Nonofficial Remedies as a brand of Ichthammol, N. F.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

### NORTH EAST BRAND TOMATO JUICE

**Manufacturer.**—North East Preserving Works, Inc., North East, Pa.

**Description.**—Tomato juice containing in high degree the natural vitamin values. Seasoned with salt.

**Manufacture.**—Selected tomatoes are harvested at the proper degree of maturity, inspected, graded, washed and again sorted, trimmed and cored by hand. The tomatoes are then chopped and heated in steam jacketed coils without exposure to air or live steam, after which they are forced through screens to extract the juice. Salt is added to the reheated expressed juice and it is immediately bottled or canned and processed.

**Analysis** (submitted by manufacturer).—Moisture 93.7%, total solids 6.3%, ash 0.7%, fat (ether extract) 0.1%, protein
